

Tributary Reports

Integrated Trends Analysis Team

Jeni Keisman, Rebecca Murphy, Renee Karrh, Mike Lane, Olivia Devereux,
Jimmy Webber, Qian Zhang

What are the Tributary Reports?

Tributary basin reports are being compiled for 11 major tributaries or tributary groups in the Chesapeake Bay Watershed.

1. MD Upper Western Shore:
 - Bush, Gunpowder, Middle Patapsco/Back
2. MD Lower W. Shore:
 - Severn, Magothy, Rhode/West, Patuxent
3. Patuxent
4. Potomac
5. Rappahannock
6. York (includes Mattaponi and Pamunkey)
7. James (includes Elizabeth and Lafayette)
8. MD Upper Eastern Shore:
 - Northeast, Back Creek, Elk, Sassafras, Chester, Eastern Bay
9. Choptank, Little Choptank, Honga
10. Lower E. Shore:
 - Fishing Bay, Nanticoke, Manokin, Wicomico, Big, Pocomoke, Tangier

Purpose

To summarize:

- How tidal water quality has changed over time;
- How factors that we believe drive those changes have changed over time;
- Scientific insights that have advanced our ability to connect water quality change to its drivers.

End Users

- Technical managers within jurisdiction agencies
- Local watershed organizations (Riverkeepers, etc.)
- Researchers (e.g. federal, state, academic)
- Other?

Goals: What do we want people to get out of these reports?

For technical managers and watershed organizations:

- A summary of how your river is doing and how that has changed over time
- An understanding of the factors that affect water quality in your basin, and how those have changed over time
- A snapshot of the level of implementation in your basin for major BMPs that can improve water quality

For researchers:

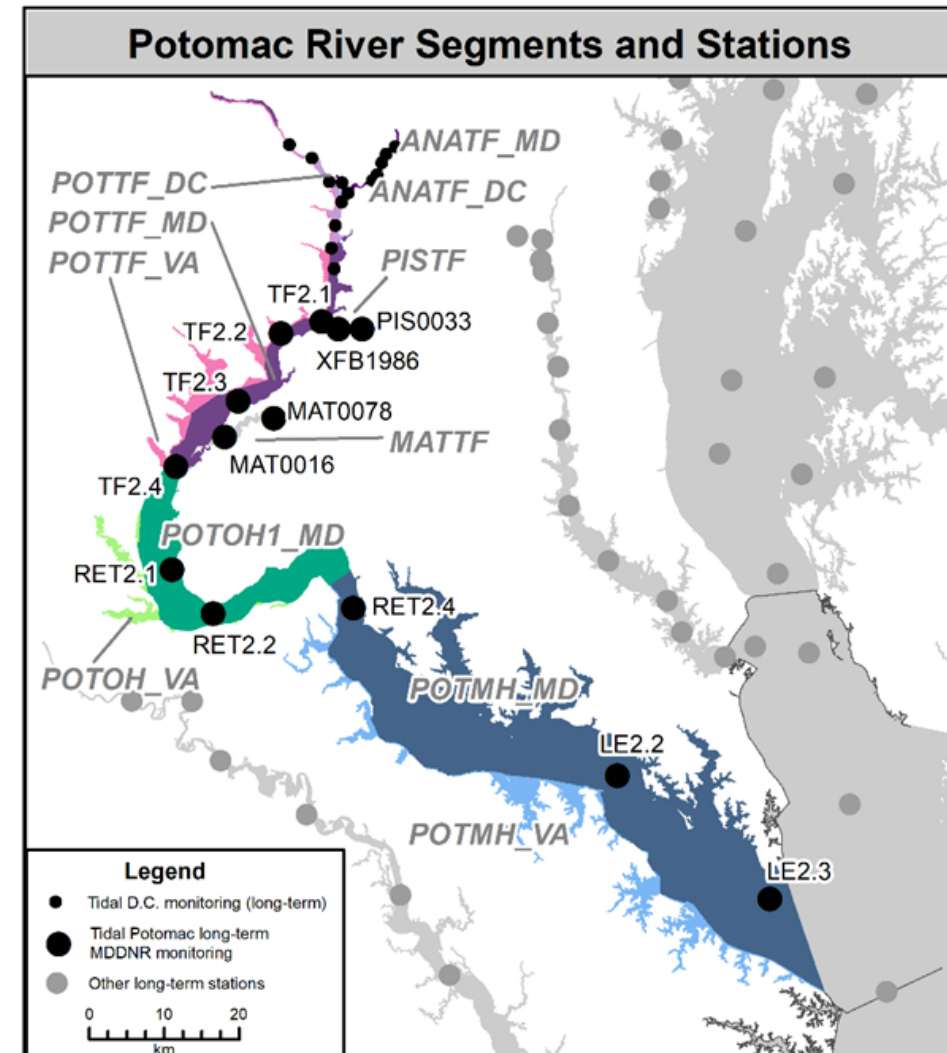

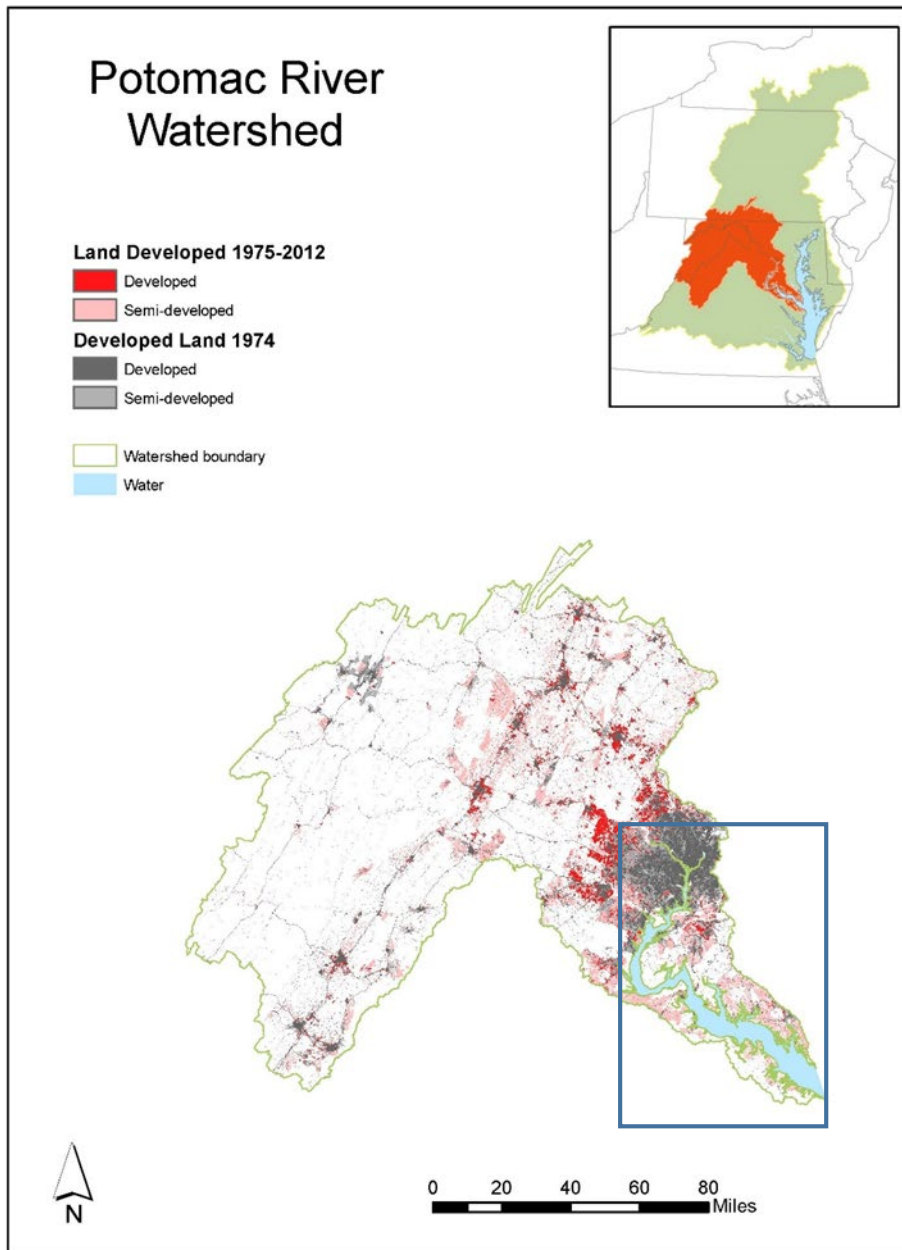

- All of the above, plus:
- Serve as a vehicle for discussion and hypothesis testing to advance our ability to predict future water quality change

current attainment versus station-level trends

- The oligohaline area of the Potomac is not attaining its open water DO standard
- but DO concentrations are probably better than in the mid-1980s

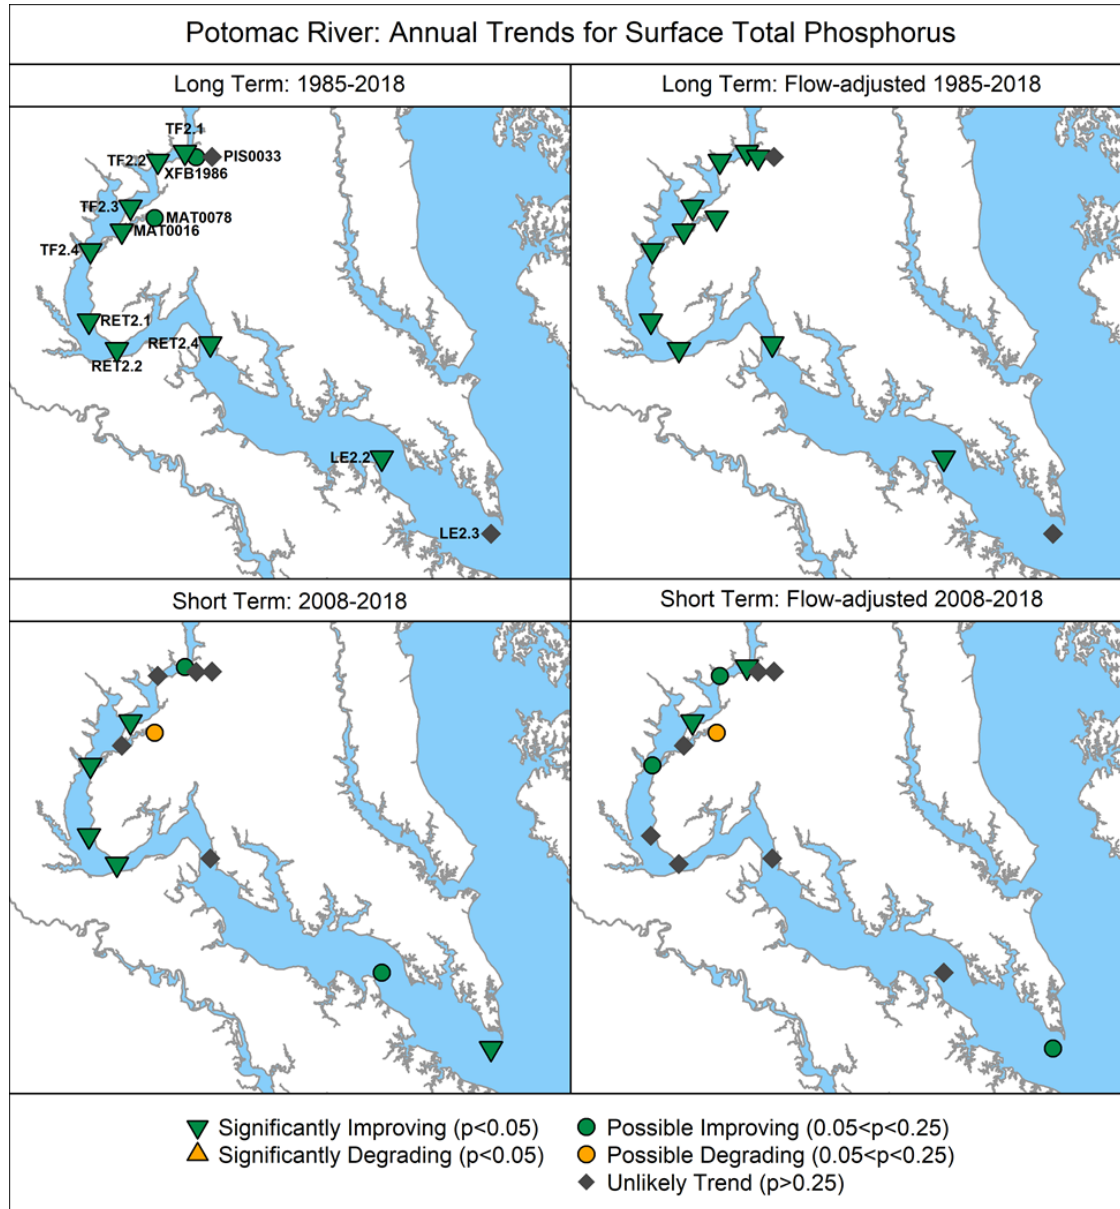

- The lower (mesohaline) Potomac is attaining the open water (surface) DO standard, but not the Deep Channel (bottom) DO standard.
- DO concentrations at the bottom of the water column haven't changed compared to the mid-1980s

Watershed Characteristics: Geology, pathway, and distance matter

From USGS, this map courtesy Zhaoying Wei

- On average, about half of the water in Chesapeake streams is derived from groundwater discharge; the other half is from soil moisture and surface runoff.
- Groundwater is generally considered the dominant delivery pathway of nitrogen to most streams in the watershed, but this varies substantially across settings.
- Soil moisture and surface runoff are generally considered the dominant pathways for phosphorus, but this also varies depending on where you are and when you measure it.
- More nitrogen load to streams in Virginia's Shenandoah Valley can be removed through in-stream processing than loads to streams in areas surrounding Washington DC, which are closer to the tidal Potomac River

Watershed Characteristics: Because geology, pathway, and distance matter

Valley and Ridge underlain by carbonate rocks (groundwater age ~ 0-10 yrs)

Piedmont crystalline settings (groundwater age ~ 0-22 yrs)

Coastal plain settings (groundwater age <1 to >100 years (median 20-40 yrs))

Soil moisture and surface runoff everywhere: days-to-months

From USGS, this map courtesy Zhaoying Wei

Preliminary Information-Subject to Revision. Not for Citation or Distribution

Watershed Characteristics: Land Use Matters

From CAST, courtesy Olivia Devereux

From Falcone 2015, courtesy Zhaoying Wei

Watershed Characteristics Translate to Nutrient and Sediment Loads

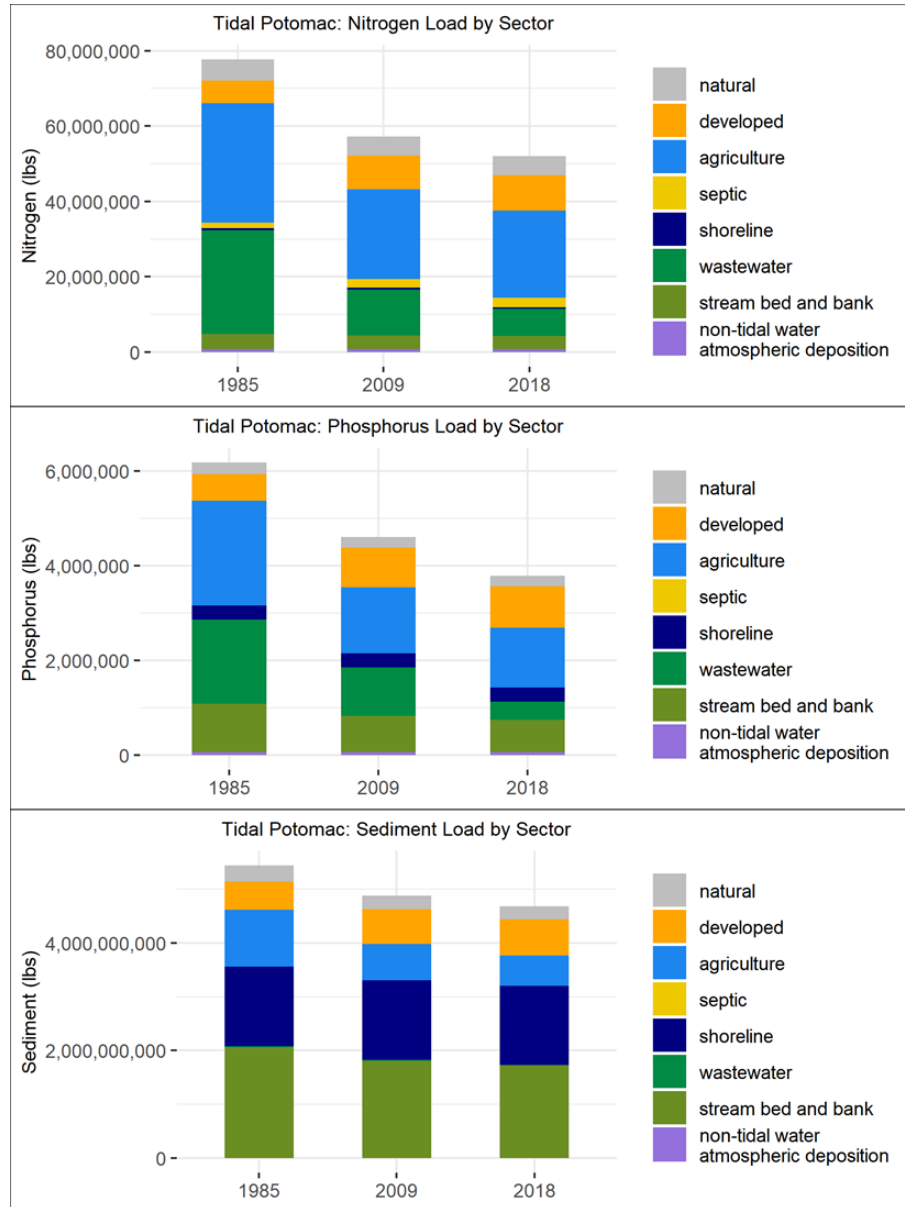

Estimated loads to tidal portions of Chesapeake Bay tributaries are a combination of:

- Monitored fluxes from USGS River Input Monitoring (RIM) stations located at the nontidal-tidal interface, and
- Below-RIM simulated loads from the Chesapeake Bay Program Watershed Model (CBWM).

Constituent	Change 1985-2014	p-value (MK)	Percent Fall-Line
TN	(11,257,117)	0.05	~ 72%
TP	(1,838,653)	0.94	~ 81%
SS	(2,696,070,671)	0.80	~ 69%

Watershed Change → Tidal Water Quality: What is expected?

Overall, changes in population size, land use, and pollution management controls between 1985 and 2018 are **expected** to change nitrogen, phosphorus, and sediment loads to the tidal Potomac River by -33%, -39%, and -14%, respectively (CBP Watershed Model Phase 6)

Source	Expected Change 1985-2018 (%)

Watershed Change → Tidal Water Quality: What is expected?

Explaining Change: What is the relative importance of each of these factors?

Watershed
Characteristics

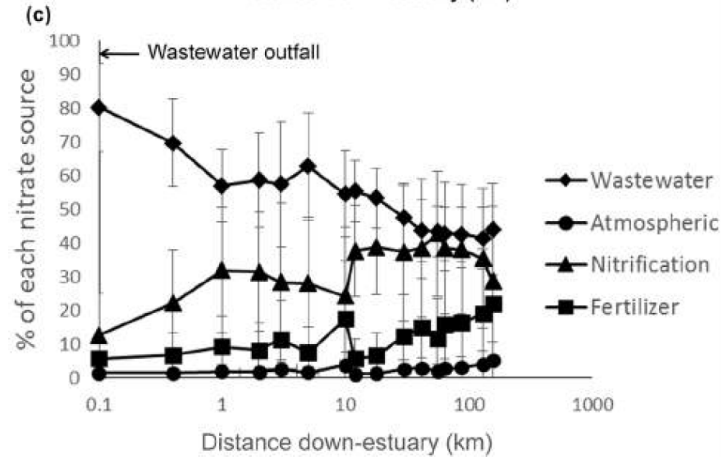

Explaining Change: Incorporating research insights

WWTP loads do reach the mouth of the river

- Nitrate at mouth of Potomac:
- Almost 50% from wastewater in the summer and fall;
- About 6-7% in winter and spring, while other nonpoint sources dominate

Pennino et al. 2016

Where wastewater is a dominant nutrient source, local water quality and habitat conditions improve after WWTP upgrades.

Boynton et al. 2013

When bivalve populations reach sufficient numbers, local water clarity and SAV respond

Potomac Tributary Trends Summary

Total nutrient concentrations have been decreasing at most stations in the Potomac River over the long-term, with improvements persisting in the last 10 years as well.

- These trends follow from the decreasing discharge from TN and TP sources in the watershed.

Despite the overall improvements in both nitrogen and phosphorus concentrations observed in these studies and in the current trend results, many of the chlorophyll-a and secchi trends are still degrading.

- Research suggests that there is a “saturation limit” for phytoplankton use of nutrients (Buchanan et al., 2005; Fisher and Gustafson, 2003). There may not be a response in phytoplankton to nutrient reductions unless the dissolved nitrogen or phosphorus concentrations cross under their saturation limits.

Recent improvements in oxygen concentrations are promising.

- That lower Potomac chlorophyll-a concentrations have either leveled out or improved may suggest a smaller amount of phytoplankton biomass available to fuel summer oxygen depletion.

Other factors such as import of nutrients from the mainstem bay (Pennino et al., 2016), varying bivalve populations (Phelps, 1994), SAV populations, and temperature increases (Ding and Elmore, 2015) could all be playing a role in the response trajectory of the Potomac River for all of these parameters.

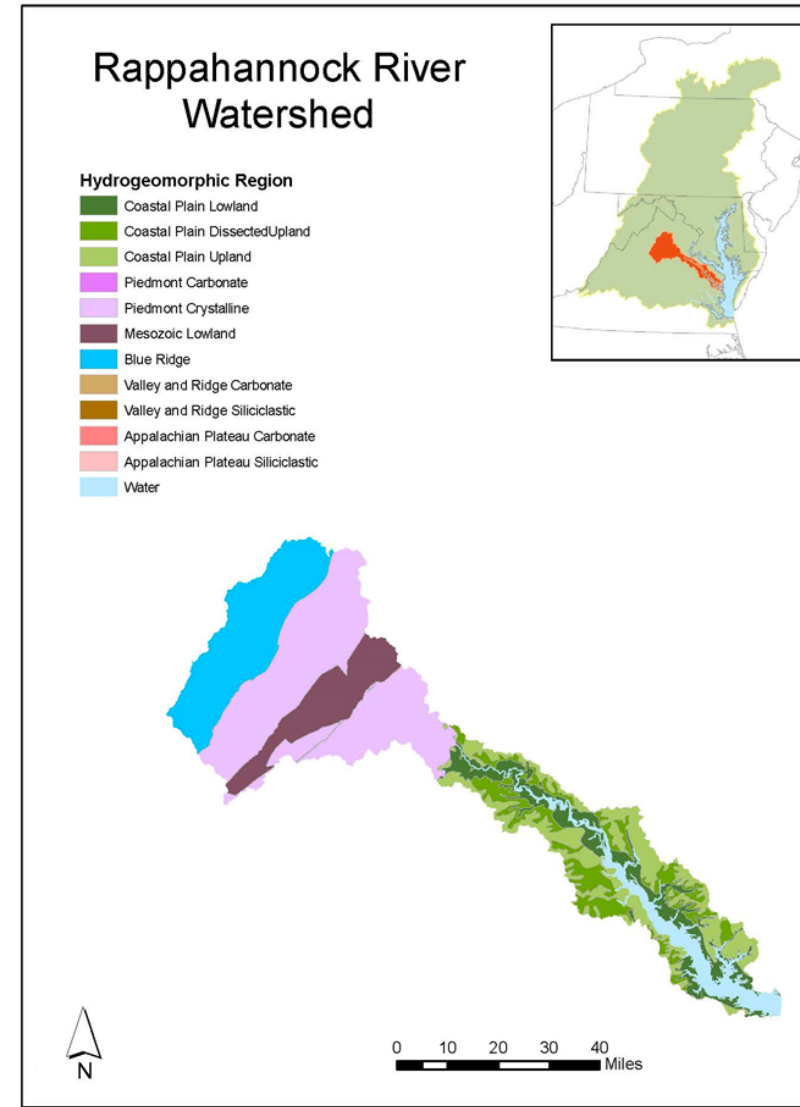

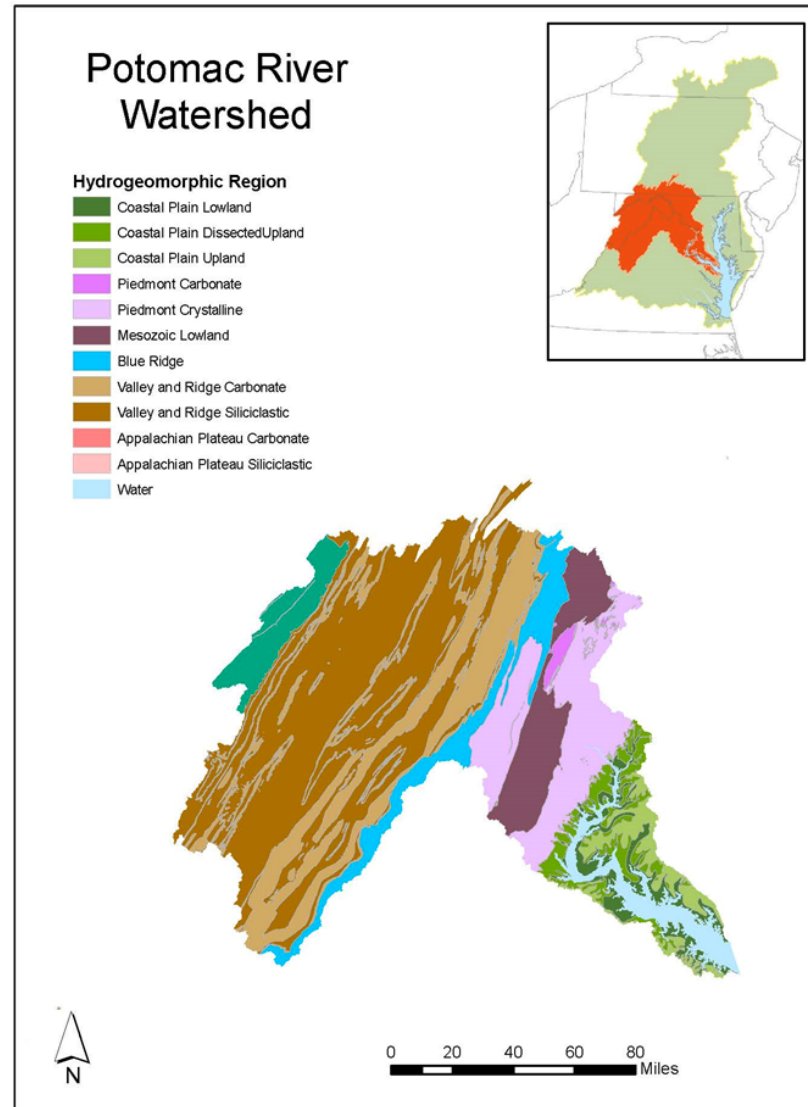

Appendix

This will be a separate document, but a map and panel plot each for:

- Bottom TP
- Bottom TN
- Surface PO₄
- Surface DIN
- Surface TSS
- Surface DO
- Surface Temperature
