

# Stream Health Outcome

## *Management Strategy*

### Introduction

Restoring health to local rivers and streams not only benefits the fish, wildlife and people using them, but also is a necessary step toward meeting water quality standards in the Chesapeake Bay. Over 100,000 stream miles drain the vast Chesapeake landscape and connect it to its receiving water body – the Chesapeake Bay. Many of these streams are impaired, and management actions are needed to improve the physical, chemical and biological functions of such streams while the health of intact streams is maintained, thereby increasing the net functional stream network across the watershed. Because stream health is affected by numerous factors, both on the land and in the water and resulting directly or indirectly from human activities, the success of this strategy recognizes an inherent connection to actions under other outcomes, such as wetlands, forest buffers, brook trout, healthy watersheds, toxic contaminants and implementation of water quality best management practices.

Deleted: is

## I. Goal, Outcome and Baseline

This management strategy identifies approaches for achieving the following goal and outcome:

**Vital Habitats Goal:** Restore, enhance and protect a network of land and water habitats to support fish and wildlife, and to afford other public benefits, including water quality, recreational uses and scenic value across the watershed.

**Stream Health Outcome:** Continually improve stream health and function throughout the watershed. Improve health and function of 10 percent of stream miles above the 2008 baseline for the Chesapeake Bay watershed.

This outcome would be tracked via improvements in the Chesapeake Bay-wide Indicator of Biotic Integrity (Chessie-BIBI). The Chessie BIBI is derived using individual state benthic macroinvertebrate data collected based on a common methodology agreed to by the Bay Program's Nontidal Monitoring Workgroup.

**Deleted:** This outcome was derived using the Chesapeake Bay-wide Indicator of Biotic Integrity (Chessie-BIBI). The development of the Chessie BIBI assessed state-collected benthic macroinvertebrate data based on methodology agreed to by the Bay Program's [Nontidal Monitoring Workgroup](#).<sup>11</sup>

For purposes of this strategy, the definition of stream health and function is to improve 10 percent of stream miles above the 2008 baseline for the Chesapeake Bay watershed. The definition of stream health and function for this restoration-based outcome thus differs from the Healthy Watersheds Outcome definition that focuses on maintaining "healthy waters and watersheds" using individual states criteria, rather than adopting a Bay-wide definition. As the Stream Health Outcome includes a Bay-wide metric to measure the improvement in stream health and function, the Management Strategy proposes a function-based definition of stream health that provides the ability to report and track incremental improvements in stream health achieved from functional lift. In addition to the primary benefit of providing riverine habitat for fish, shellfish and wildlife, stream restoration also is a recognized best management practice for water quality and will provide a secondary benefit of reducing nutrient and sediment loads to achieve the target load reductions as part of the Chesapeake Bay total maximum daily load (TMDL) ([Table 1](#)).

Table 1. Chesapeake Bay Watershed WIP progress and 2025 targets for stream restoration (units in feet). Source CBP

	2009 Progress	2011 Progress	2013 Progress	2025 WIP Commitment
<b>Urban Stream Restoration</b>	165,375	208,509	385,190 (17%)	2,332,664
<b>Non-Urban Stream Restoration</b>	191,638	501,120	1,041,234 (92%)	1,128,757
<b>Total</b>			1,426,424 41%	3,461,421

**Baseline and Current Condition:** Between 2000 and 2010, more than 14,000 stream sites were sampled and rated for biological integrity. Based on the Chessie BIBI, 43 percent of the streams were in fair, good, or excellent condition. Fifty-seven percent of the streams were in very poor or poor condition. The baseline is being re-evaluated in 2015 by ICPRB and an ad-hoc team formed

**Deleted:** , or approximately 57,000 stream miles of the 100,000 stream miles in the Bay watershed

from various CBP workgroups and this work will be included and tracked as part of this strategy's biennial workplan.

CBP uses the Chessie BIBI as a "stream health indicator"<sup>1</sup>. Index results were included in CBP *Bay Barometer* reports between 2008 and 2012. The index is mentioned specifically as a measure of stream restoration progress in the 2009 Executive Order 13508, Draft Strategy for Protecting and Restoring the Chesapeake Bay. It is a biological endpoint that will reflect the improvements in stream health and function called for in the 2014 Chesapeake Watershed Agreement. At this time, the index needs to be updated with the most recent macroinvertebrate data. It is now possible to develop and test genus-level metrics to incorporate into the index, and further test the index's sensitivity to various stressors such as altered or degraded water quality, energy source, physical habitat, flow regime, and biotic interactions. A 2008 baseline needs to be established against which progress can be measured.

**Deleted:** (e.g., water quality, physical habitat

While the Chessie BIBI provides a rating of stream health, the data and methods used for its derivation limit annual trend analysis to document changes with time. Further, the Chessie-BIBI provides information about the biological condition of streams, and stream functions which support that condition may only be inferred. Robust statistical analysis of the data has shown significant relationships between watershed stressors and Chessie BIBI. Watershed and stream metrics derived from routinely collected, non-biological monitoring data (e.g., land use land cover, water quality) could be used to detect changes in stream health and function, in addition to biological function, that occur between 2008 (or baseline period) and 2017. These metrics can contribute to a broader understanding of goal attainment for the Stream Health Outcome and be used to expand the geographic extent of stressor identification and prioritization analysis.

## II. Participating Partners

Team Lead: Vital Habitats Goal Team

Workgroup Lead: Stream Health Workgroup

Opportunities for Cross-Goal Team Collaboration: Fisheries Goal Team, Water Quality Goal Team, and Healthy Watersheds Goal Team

Active Current Participation and Role (**Signatory agencies in bold**):

### **Level of Participation: High**

- Interstate Commission on the Potomac River Basin (ICPRB)  
*Re-evaluation of Chessie BIBI to update baseline*
- US Geological Survey (USGS)  
*Development of Chessie BIBI, monitoring data of streams and their assessment*
- US Fish & Wildlife Service (USFWS)  
*Co-Chair Stream Health Work Group; Manages and implements stream restoration projects, provides training on stream restoration assessment methods and development of guidance*

<sup>1</sup>

[http://www.chesapeakebay.net/indicators/indicator/health\\_of\\_freshwater\\_streams\\_in\\_the\\_chesapeake\\_bay\\_watershed](http://www.chesapeakebay.net/indicators/indicator/health_of_freshwater_streams_in_the_chesapeake_bay_watershed)

- US Army Corps of Engineers (USACE)  
*Review and approval of stream restoration projects*  
USACE cost-shares stream and floodplain habitat restoration projects under its ecosystem restoration mission. Under administration policy, USACE does not generally cost-share projects undertaken for principal purpose of water quality improvement
- **EPA Region III**  
*Review and approval of stream restoration projects*
- **EPA Chesapeake Bay Program Office (CBPO)**  
*Partnership of federal, state and resource agencies to restore Chesapeake Bay*
- Center for Watershed Protection (CWP)  
*Sediment Reduction and Stream Corridor Analysis Coordinator for the CBP, Co-Chair Stream Health Work Group*
- Virginia Tech (VT)  
*Member of STAC, Stream Health Work Group Drafting Team*
- **Chesapeake Bay State (VA, MD, WV, DE, PA, NY) and District of Columbia natural resource, stormwater and permit approval agencies**  
*Monitoring stream conditions and health, implements/manages stream restoration projects and other BMPs, provides funding to support project implementation. Review and approval of stream restoration projects*
- Chesapeake Bay Trust (CBT)  
*Co-Chair Habitat GIT, lead effort to organize pooled monitoring approach*
- National Fish and Wildlife Foundation (NFWF)  
*Provides funding for stream restoration projects and BMPs to reduce nutrient and sediment loadings*
- Local government  
*Responsible for implementation of BMPs to include stream restoration projects as part of the WIPs*
- Urban Stream Restoration BMP Expert Panel Members  
*Development of protocols and nutrient and sediment pollutant load reductions to credit stream restoration projects for water quality improvements*

Deleted: ty

**Local Engagement**

Local government is responsible for implementation of BMPs to include stream restoration projects as part of the WIPs.

### III. Factors Influencing

To fully achieve this outcome it is critical to address priority stressors to restore stream functions that improve local stream health, as well as the Bay. A stressor in the context of this strategy is any factor limiting to aquatic life, or stream processes, that occurs as a direct or indirect impact of current or past human actions. Stressors refer to both biological and physical properties. Many factors, with wide-ranging levels of importance and management potential, influence the attainment of the stream health outcome. A thorough understanding of ecological stressors and factors, policy/and administrative factors, and scientific knowledge and the application of research, necessary to improve stream health and function at both the local and Baywide-scales is needed. Depending upon the type of stressor, the biological, chemical, and/or physical conditions of the stream ecosystem may be impacted.

Ecological stressors & factors are the physical, chemical and biological factors that impair or limit stream health recovery. They may also be watershed-based factors that limit stream function(s) or negatively affect downstream waters. These factors affect stream health at two scales - local and downstream waters to the Bay. Management actions are needed to reduce or remove these factors to improve stream health such as stream restoration and upland BMPs that reduce the delivery of excessive pollutants and runoff. Improvement in local streams overall is paramount to achieving this Outcome. Many of the factors listed are contributing pollutants to 303(d) listed impaired waters for which local TMDLs are established. Ecological stressors and factors influencing the Outcome include:

Within the stream channel and floodplain factors:

- Excessive sediment and nutrients in-stream from unstable stream banks and legacy sediments in the floodplain
- Limited nutrient and organic processing-instream
- Alteration in channel form and function resulting in instability and disequilibrium affecting diversity and quality of habitat
-  Concentrated flows and reduction in baseflows
- Piped and channelize streams
- Removal/Loss of forested riparian areas and the benefits provided by shading
- 

Watershed-based factors:

- Impervious cover and increases in stormwater runoff
- Significant changes in watershed hydrology (time of concentration) related to overland flow impacted by road drainage, ag land drainage, driveways, stormwater collection systems, etc.
- Flow alteration and flashy hydrology
- Excessive nutrient loading to streams from excess untreated runoff (agricultural and urban) from the upland areas in the watershed and groundwater
- Implementation of stormwater management controls (e.g. BMPs)
- Leaky wastewater infrastructure
- Toxicity of effluent from resource extraction activities (i.e., acid mine drainage, fracking)
- Road de-icing practices (salt)
- Thermal impacts
- Invasive species
- Endocrine disrupting chemicals

**Moved (insertion) [2]**

**Moved (insertion) [1]**

**Formatted:** Indent: Left: 0.5", No bullets or

**Deleted:** ¶

Policy and Administrative factors limit the implementation potential of an action. Key among these factors are related to the permit approval process, that despite approval of many projects throughout the Chesapeake Bay, there are projects that encounter delays during the permit review process hindering, significantly in some cases, their implementation. Uncovering factors that are common to both the practitioner and regulator need to be overcome to address this barrier to implementation. The current assessment of jurisdictions to meet their 2017 and 2025 WIP targets heightens the need to address these factors to implement projects that meet the sediment and nutrient loads reductions necessary to improve stream health. Factors that influence the outcome include:

- Review and approval of stream restoration projects for WIP implementation "Detailed content for this factor pending previously requested input from State natural resource/regulatory agency contacts, or key partner organizations. Input to be provided by March 6 during course of Management Board review."
- Lack of common watershed, stressor and stream assessment and restoration guidelines
- Integration of water quality and living resource goals during WIP stream restoration
- MS4 permits focus on water quality
- Adequate financial resources to support local implementation efforts
- Adequate extension infrastructure to communicate newest research and technical guidance to jurisdictions
- In very urban area, the availability of land to retrofit and implement upland BMPs

Scientific Knowledge & Application of Research are factors related to our current understanding of streams and their response to management interventions and the ability to effectively translate the most up-to-date scientific understanding into effective policy and regulatory guidance. Factors that influence the outcome include:

- Robust stream restoration monitoring to evaluate the potential functional lift or improvement in stream functions from BMP implementation
- Possible lag times that affect the ability to evaluate the effect of upland BMP on stream health
- Research needed to guide the selection of achievable reference conditions/design approaches based on watershed and stream functions to include an urban reference continuum
- Insufficient data to develop Bay-wide fish-based indicator to complement macro-invertebrate indicator (Chessie BIBI)
- Lengthy timeframe for adjusting BMP credit or recognizing new BMPs
- Limitations of the applicability of the Chessie BIBI (and other similar ecological data) to streams where restoration work is being conducted on an annual basis.
- Identify nutrient hotspot in stream valley where erodible geologic materials and soils contain excess nutrients
- Additional research to refine nutrient credits for stream restoration projects as supported by the Expert Panel recommendations on Individual Stream Restoration Projects to include for example bioavailability of nutrients.

**Deleted:** Key among these factors are the issuance of permits for stream restoration projects and the regulatory and policy guidance available for stream corridor restoration projects to demonstrate functional lift

**Deleted:** <#>Suitability of existing approach to define reference conditions for restoration efforts¶

**Deleted:** to

**Formatted:** Indent: Left: 0.5", No bullets or

Because the definition of stream health and function for this restoration-based Outcome uses a Bay-wide metric to measure the improvement in stream health and function, this Strategy proposes a function-based definition of stream health that provides a common framework for reporting and tracking incremental improvements in stream health based on functional lift. For example, the IBI aggregates multi-function improvements, while a disaggregation would help to determine a finer resolution of stream health indicators.

Healthy streams support and maintain basic functions associated with either structure or processes (Fischenich 2006). Stream functions are the physical, chemical and biological processes that support and sustain a stream's ecology. While there are a number of ways in which stream functions may be defined (see [Table 2](#)), they are synergistic, or hierarchical in their function such that the quality and condition of each stream process impact others. Therefore, the processes and functions that are most critical to improve stream health will vary depending on what the stressors are for a stream and which of those stressors must be reduced or removed.

#### IV. Gaps

The Habitat GIT, together with the Health Watersheds GIT recognize that streams are on a spectrum of health from those that are deemed impaired to those that the states have identified as being outstanding and healthy. The Stream Health and Healthy Watersheds outcomes are complementary in that one focuses on improving the degraded streams while the other works to maintain one-hundred percent of state-identified current healthy waters and watersheds. Streams that are in the 'middle' – or marginally healthy – are at potential risk of being overlooked. Yet, these marginal streams are the ones with the potential to rise to the level of being identified as 'healthy' waters by the states. In the meantime, actions need to be taken to prevent these marginal streams from further degradation. Streams have degraded over time and further research is needed to understand and predict how the streams will react to anthropogenic and natural pressures. There is a data gap that needs to be addressed in order to develop a method to track the improvement/degradation of the marginal streams.

##### Information & Data

- Benthic macroinvertebrate data from enough streams with enough frequency to track progress over time. Chessie BIBI provides limited capacity for annual tracking, trend analysis less than 5-7 yrs.
- Bay-wide and stream metrics other than biological indices, such as the Chessie BIBI, to assess physical and chemical health and functions of streams
- Update or review of methods to define reference conditions or endpoints for streams
- Sufficiency of data to demonstrate effectiveness of stream restoration practices
- Sufficiency of data to demonstrate restoration of stream processes following installation of upland watershed BMPs. Sufficiency
- Cumulative effects and interactions between stressors

##### Regulatory & Programmatic

- Uniform project design process for stream restoration that can measure change in stream functions and/project success based on a project goals and objectives. Specific to the Bay TMDL, a design process for restoration projects to reduce nutrient and sediments loads delivered downstream while at the same time ensuring optimal habitat conditions restored.
- Information needs to support innovative, effective design approaches to identify restoration potential and success for different land uses, stream types, and current and future site constraints, causes of impairment/stressors (e.g. legacy sediment, contaminants in water and sediment, runoff volume and velocity).
- Identification of local and watershed priority stressors that affect local stream health and management actions to results in associated function lift
- Coordinating/collaborating with other Goal implementation teams focused on stream condition (e.g., Maintain Healthy Watersheds GIT). *"Detailed content for this gap pending requested input from Maintain Healthy Watersheds GIT. Input to be provided by March 6 during course of Management Board review."*

Deleted: vs

Deleted: .

Prioritization

- Targeting procedures for cost-effective restoration actions and design approaches that will achieve both water quality and biological functional improvement. WIPs provide a level of analysis on the type and mix of projects to meet load reductions and associated costs. The process to identify the projects varies by jurisdiction along with cost estimates.
- Investments in research to improve the body of knowledge surrounding restoration techniques and net benefit to stream and watershed health.

## V. Current Efforts

Development of 2008 Baseline for the Chessie BIBI

The Interstate Commission on the Potomac River Basin received funding to re-evaluate the Chessie BIBI and to provide an update to the 2008 baseline.

Guidance to Evaluate Stream Restoration Projects

The U.S. Fish and Wildlife Service and Maryland Department of Environment plan to publish guidance to evaluate stream restoration projects using a function-based assessment process (i.e., Stream Functions Pyramid Framework). Release of the guidance is expected in 2015. Much post-construction data regarding the response of various stream functions to restoration and other BMPs will be needed to implement this process. Identifying gaps in existing knowledge will be important to determine its applicability.

STAC Workshop on Designing Sustainable Stream Restoration Projects within the Chesapeake Bay Watershed

The Habitat Goal Implementation Team hosted a workshop in May 2014 to create agreement among practitioners, regulators and scientists on a common language and assessment methods for designing sustainable stream restoration projects that improve the functional elements of stream health.

Pooled Monitoring Approach to Stream Restoration Projects

During the summer and fall of 2014, an ad-hoc committee represented by regulatory agencies (USACE, EPA, MDE, FWS), other state agencies (MDE, MD DNR, MD SHA), stream organizations (MSRA), local government (Anne Arundel County) was coordinated and lead by the Chesapeake Bay Trust to explore and begin development of a pooled monitoring approach. In most cases, the data currently generated from permitted stream restoration projects are insufficient to assess the functional improvement, or uplift, as a result of management actions. While other factors affect the ability to assess the impact of stream restoration projects, the identification of specific monitoring parameters that align with project goals and objectives is needed. A Request for Proposals was released by this committee through the CBT to answer research questions that will ultimately lead to an increased confidence in stream restoration project outcomes, clarification of the optimal site conditions in which to apply particular stream restoration techniques, information useful to regulatory agencies in project permitting and information that will help guide monitoring programs.

Ongoing Monitoring Efforts

There are several state and resource agency monitoring programs to support the assessment of stream health and function at the state level. These can be used along with the Chessie BIBI to track stream

health toward meeting the goal of the Management Strategy. Each of the data sets have unique advantages for use in tracking. Examples of some of these efforts include:

- EPA National Rivers and Stream Assessment: The EPA NRSA sampled between 90 and 100 randomly selected sites in the Chesapeake Bay watershed. These sites have benthic invertebrate, fish, periphyton, water quality and habitat data. The EPA NRSA surveys are conducted every five years, including 2008/2009, 2013/2014, with the next one scheduled for 2018/2019.
- State 305b (Integrated Report) Reports (e.g. see [http://www.mde.state.md.us/programs/Water/TMDL/Pages/Programs/WaterPrograms/tmdl/bid\\_studies.aspx](http://www.mde.state.md.us/programs/Water/TMDL/Pages/Programs/WaterPrograms/tmdl/bid_studies.aspx). Accessed Jan 15, 2015.)
- Tidal Network monitoring sites
- Non-Tidal Network monitoring sites
- National Park Service has five inventory and monitoring networks operating within the Chesapeake Bay (provided by Marian Norris);
- Maryland Biological Stream Survey (MBSS): Sampled 252 randomly selected sites during 2007-2009 to characterize Maryland's ecological condition. Round Four is scheduled for 2014-2018.
- County monitoring programs

#### Chesapeake Bay Regional General Permit for TMDL

The Baltimore District of the U.S. Army Corps of Engineers (Corps) released a draft Regional General Permit for TMDL in May 2014 for activities in waters of the U.S., including jurisdictional wetlands that that covers activities within Maryland and the District of Columbia whose purpose is to meet nutrient and sediment load reduction targets under the Chesapeake Bay TMDL mandates for these jurisdictions (e.g., Chesapeake Bay TMDL Watershed Implementation Plan (WIP). Activities authorized by this TMDL RGP include, but are not limited to, the retrofit of existing stormwater management facilities, the retrofit of existing stormwater management outfalls, and the restoration and enhancement of non-tidal streams and non-tidal wetlands. Stream and wetland restoration and enhancement projects must meet nutrient and sediment load reduction targets under the Chesapeake Bay TMDL and restore or enhance aquatic resource functions at the project site. The RGP is currently draft and not final as of the publication date of the Management Strategy.

**Deleted:** July

**Deleted:** are part of an overall watershed strategy

**Deleted:** ) whose purpose is to meet nutrient and sediment load reduction targets under the Chesapeake Bay TMDL mandates

#### MS4 permits that have incorporated Bay TMDL goals

Integration of efforts to implement BMPs to coordinate management actions to address both MS4 permit requirements along with nutrient and sediment load reductions for the Bay TMDL.

#### WIP implementation of BMPS

The Chesapeake Bay TMDL is designed to ensure that all pollution control measures needed to fully restore the Bay and its tidal rivers are in place by 2025, with at least 60 percent of implementation by 2017. WIPs detail how and when the Bay jurisdictions will meet their pollution load allocations. The progress for WIP implementation is reported annually to the Chesapeake Bay Program. BMPs that most notably influence stream health include runoff-reduction urban BMPs and agricultural BMPs such as stream fencing, forest buffers, grass buffers and wetland restoration.

Approximately 700 miles of stream restoration projects are expected to be implemented to achieve the nutrient and sediment load reductions required by the Chesapeake Bay TMDL. As a result, the projected implementation rate of stream restoration projects to meet the 2017 and 2025 timelines with the Bay

watershed is unprecedented. Based on the planned 2025 Phase II WIPs, the Chesapeake Bay Program reports that approximately 41 percent of planned stream restoration projects were implemented based on the 2013 progress reported by the Chesapeake Bay jurisdictions (NY, PA, MD, WV, VA, DE, DC), with 92 percent of the projects located in areas with non-urban land use.

*Table 3: Stream restoration projects identified in the Phase II Watershed Implementation Plans (in feet) for 2025*

Jurisdiction	NY	PA	MD	VA	WV	DE	DC	CBW
Non-urban	337,999	529,435	73,975	104,528	19,618	63,202	0	1,128,757
Urban	26,500	55,000	2,527,626	116,399	0	200	42,240	2,332,664
Total	364,499	584,435	2,601,601	220,927	19,618	63,402	42,240	3,461,421 (655 mi)

#### Development of Chesapeake Bay BMP Verification

In August 2014, the Management Board approved a framework<sup>2</sup> by which the Bay Program partners will develop verification programs to ensure that implemented BMPs continue to work properly and are eligible to receive nutrient and sediment load reduction credits towards the TMDLs. The framework includes BMP verification guidance from the Bay Program's six technical sector and habitat workgroups (e.g., agriculture, forestry, urban, wastewater, wetlands, and streams). While the recommended verification guidance is specific to the source sector BMPs, there are over-arching principles to which the guidance is based: practice reporting, scientific rigor, public confidence, adaptive management and sector equity.

## VI. Management Approaches

This management strategy is based on a holistic approach to improve stream health and function. The following major points are fundamental to the Stream Health Outcome Management Strategy for which actions are defined. This outcome recognizes:

- The health and function of streams affects the local stream environment as well as the downstream waters to the Bay.
- Streams are a part a system that includes the stream corridor, floodplain, wetlands and watershed, and as such, stream health is affected by both in-stream and watershed functions, processes and characteristics.
- Measures that would improve stream functions may occur in the stream itself, in the floodplain or in the watershed. Some measures could serve to meet more than one outcome of the Bay Agreement.
- Stream functions related to nutrient and sediment delivery to the Bay are of fundamental importance because of their explicit inclusion in the Bay Agreement.

<sup>2</sup> "Strengthening Verification of Best Management Practices Implemented in the Chesapeake Bay Watershed: A Basinwide Framework. Prepared by the Water Quality Goal Implementation Team's BMP Verification Committee.

Figure 1 is a conceptual illustration of this management approach showing that improvement to stream health relies upon the ability to identify the key factors that affect critical stream functions. The key factors influencing the outcome are described in Section III and include: ecological stressors and factors, policy and administration, and scientific knowledge and the application of research. Management actions identified to address these factors are directed to remove or reduce the impact of the ecological stressor that is affecting stream function(s). Metrics are needed that quantify the effect of removing that stressor (e.g. excessive sediment) on stream response (e.g. water quality improvement). The ability to improve stream health and function is not only limited by the ability to identify the ecological stressor(s), it is also affected by policy and administration factors that may limit implementation potential of an action. For example, sufficient monitoring data to demonstrate the effectiveness of stream corridor restoration projects or new design approaches may limit permit approval, or the ability to effectively translate the most up-to-date scientific understanding into effective policy and regulatory guidance. The ability to assess progress toward the outcome will rely on the collective effect of individual actions as measured by indices of stream ecological condition (e.g., Chessie BIBI) from streams throughout the watershed, while incremental improvements may be assessed by information generated at the site-specific project scale to provide a forecast of future assessment at more regional scales.

Figure 1. Schematic for Stream Health Outcome Management Strategy

Strategies to attain the Water Quality Goal outcomes (2017 WIP, 2025 WIP, Water Quality Standards and Attainment and Monitoring) complement this outcome as actions to reduce or remove stressors or factors affecting stream health may also be related to watershed activities. As such, implementation of BMPs to reduce nutrient and sediment pollution load reduction necessary to achieve water quality

standards would contribute toward improving stream health. Perhaps more important, however, is the implementation of upland BMPs that reduce the volume and rate of stormwater runoff entering streams, assisting in efforts to restore ecologically sustainable flow regimes. Similarly, the practices and controls put into place that reduce and prevent the effects of toxic contaminants below levels that harm aquatic systems and human would have a similar affect (Toxic Contaminants Outcome). Further, other outcomes that increase the wetland acreage and forested buffers in the watershed would also support improvement in stream health and function as they address the removal or reduction in priority ecological stressors and factors. Overall, the Strategy recognizes the need to identify principal stressors affecting stream health if maximum in-stream uplift is going to be achieved, then identify and promote measures to remediate principal stressors through implementation actions (USEPA, 2014).

The following five strategies are specific to the Stream Health Outcome, focusing on a well-developed, broadened application of a function-based approach to stream restoration. A function-based approach is not only central to the permit and review process, but also is recognized by researchers as a sound approach to restoration when implemented using a well-defined project process (e.g. with clearly articulated project goals and objectives). A supplemental table is provided following the Management Strategy to illustrate the priority factors and gaps addressed by the five strategies.

#### Strategy 1:

"Identify an appropriate suite of metrics to measure the multiple facets of stream health to complement the baywide Chessie BIBI.

**Deleted:** Identify an appropriate suite of metrics to measure the multiple facets of stream health

- a. Develop a definition of stream health that shows the linkage between upland drainages and local stream health, and between local stream health and the health of downstream receiving waters
- b. Develop metrics/composite indices from routinely collected, non-biological data to measure changes in stream function to assess regional improvement
- c. Include common indicators of stream functions to include for example, lateral stability, bedform diversity, habitat diversity, riparian corridor, nutrient and organic matter processing, as part of monitoring guidance for stream restoration projects to demonstrate functional lift.
- d. Align metrics of functional lift with stream restoration protocols crediting projects for the Chesapeake Bay TMDL for nutrient and sediment reduction

#### Strategy 2:

Provision of adequate funding and technical resources to support functional lift in stream restoration projects, in addition to nutrient and sediment reduction.

- a. Subwatershed monitoring studies that could explore how much upland retrofit implementation is needed to optimize functional uplift when stream restoration and stormwater retrofits are installed as part of an integrated restoration plan.
- b. Provide training to jurisdictions to implement expert panel report recommendations.
- c. Work with funding agencies to provide multi-year funding to monitor effects of stream restoration.
- d. Adopt a pooled monitoring approach for different stream restoration project designs that collectively generates data to demonstrate functional lift on a project-specific basis. Overall,

monitoring data generated from stream restoration projects should have the potential to demonstrate restored stream functions.

- e. Establishment of an on-going stream restoration monitoring consortium and data clearinghouse within the CBP Partnership to share project data.
- f. Recommend incentives for projects that provide both functional uplift and water quality benefits.

#### Strategy 3:

Ongoing coordination with state and federal stream and wetland permitting authorities to ensure that stream restoration projects used for credit in the Bay TMDL are consistently applied and meet or exceed permitting requirements established to protect waters of the US. *Detailed content for this section pending previously requested input from State natural resource/regulatory agency contacts, or key partner organizations. Input to be provided by March 6 during course of Management Board review.*

#### Strategy 4:

Develop and promote holistic stream restoration design guidelines that identifies the level of degradation and improvement of stream functions and key stressors/factors limiting potential uplift

- a. Development of function-based stream assessment framework. Current work by MDE and USFWS may be used as a template to apply in other Bay jurisdictions
- b. Develop case studies to document functional response in stream with various management interventions.
- c. Add language to MS4 permits to recognize function uplift as part of nutrient and sediment credits towards meeting the Bay TMDL
- d. Convene an expert panel similar to those available for expected nutrient and sediment reductions, to address the applicability of Chessie BIBI (and other similar ecological data) where restoration work is being conducted. Recommendations could be applied to help track estimated stream improvements similarly to the way nutrient and sediment trends are already tracked by the Bay Program.

**Deleted:** recognize functional uplift as part of credit for stream restoration projects

#### Strategy 5:

- a. Engage with local governments to inform landowners as well as the general public of beneficial stream restoration and maintenance practices, as well as individual homeowner practices (e.g. rain barrels, lawn care) and their impact on the community. Streams in the backyards of many large and small property owners, as well as public places. A programmatic approach similar to the Upper Susquehanna Coalition Emergency Stream Intervention initiative that provides outreach and technical training and assistance through a network of conservation specialists.

## VII. Monitoring Progress

Monitoring programs are critical to understanding response of stream to restoration activities – in-stream or upland areas. Federal, state, local and natural resource agency monitoring programs generate data on the physical, chemical and biological conditions of streams. These data are used to generate the Chessie BIBI. The Chessie BIBI is key to monitoring progress toward improving 10 percent of stream health and function. The strategy does not advocate for new monitoring programs. Rather, to monitor annual progress, the strategy recommends other existing data sources supplement this Bay-wide

indicator (e.g. jurisdiction-specific metrics). While minor differences in stream biological, physical habitat, and water quality monitoring methods exist, jurisdiction assessments may also be useful in tracking stream health and function over time at individual sites. Further, the development of common stream assessment and restoration guidelines would generate comparable datasets across stream restoration projects. This would provide data to characterize stream health across all stream functions so that incremental changes in stream functional lift can be reported, and support data needs for the Chessie BIBI.

The monitoring data would be based on routinely collected data to measure changes in stream functions for instream and floodplain conditions. The management strategies provide examples of the types of indicators that may be used to measure critical stream functions (e.g. lateral stability, bedform diversity, [habitat diversity](#), floodplain connectivity, riparian corridor condition, water quality and benthic macroinvertebrates, and fish) from project specific locations throughout the watershed and streams in general. The task to identify the indicators selected to support the management strategy is recommended as part of the biennial workplan, and may include these indicators, or others as the work is undertaken. Data are routinely generated from stream restoration projects as part of permit requirements but the data requirements are not necessarily comparable across projects, nor do they necessarily inform functional improvement related to nutrient and sediment delivery downstream, or stream health, in general. The ability to adopt a pooled-monitoring approach using commonly accepted stream assessment and restoration guidelines could then demonstrate the effect of design approaches and stream functional response from case studies analyses. Post-construction monitoring would also be supported by data generated and reported from the Chesapeake Bay Program verification guidance for stream restoration BMP implementation that recommends site visit and evaluations two years after construction and then every five years or after catastrophic event. Jurisdiction-specific verification guidance is under development.

### VIII. Assessing Progress

The Chesapeake Bay Program annual progress reports on BMP implementation, specifically BMPs identified to impact critical stream functions (e.g. stream restoration, stream fencing and forest buffers) can be used to estimate the project nutrient and sediment load reductions expected from practice implementation. Assessing progress should also focus on functional uplift and allow for different levels of lift based on project goals and objectives. While projects undertaken for Bay TMDL purpose focus on nutrient and sediment reduction, they should be done in environmentally sensitive manner that would restore instream and floodplain habitats. While we want to encourage biological lift for all stream restoration projects, we cannot require it given site specific constraints and the ability to address stressors affecting the health of the stream. It is important that a progress reporting process be developed that can be used to assess progress up through biology but allow for lower levels (i.e., stability) of report only.

### IX. Adaptively Manage

For any given restoration project, there are uncertainties in the application of even the best restoration science, both stream corridor restoration and upland BMPs, which includes some level of risk that implementation may not achieve its objectives. At the scale of the Chesapeake Bay watershed this

uncertainty is compounded by the extent of BMP implementation required to meet the Chesapeake Bay TMDL. The adaptive management approach to address the urban, agricultural and wastewater management measures that may improve stream health undertaken outside of the stream corridor and floodplain are addressed in the Water Quality Outcome management strategies.

As the field of watershed management, stream restoration and BMP science continue to evolve, the desired ecological endpoint for any given project may also evolve throughout the project life and through feedback from monitoring of the relevant function-based parameters. Further, understanding the response in stream health to a management action is affected by nature itself to include lag times but also the interactions amongst many stream functions. For example, the improvement in biological stream function will take a longer time period compared to improved flow regimes. In short, the understanding of stream process functions and the interrelationship with the watershed will continue to advance with implementation in the field. A process that communicates the current state of the science on the influence of efforts to improve stream health now, with periodic updates, would help ensure the most successful practices are implemented and the most benefits possible for stream health are achieved.

Supplemental Table. Stream Health Outcome Strategy, Priority Factors Influencing and Gaps Addressed by the Proposed Stream Health Outcome Management Strategy with Potential Indicators to Track Progress Towards Achievement

DRAFT

Management Strategy	Priority Factors Influencing	Gaps	Potential Indicators
Strategy 1: Identify an appropriate suite of metrics to measure the multiple facets of stream health.			
e. Develop a definition of stream health that shows the linkage between upland drainages and local stream health, and between local stream health and the health of downstream receiving waters	<ul style="list-style-type: none"> <li>Lack of common watershed, stressor and stream assessment restoration guidelines</li> <li>Integration of water quality and living resource goals during WIP stream restoration project implementation</li> <li>See list of ecological stressors and factors where the def'n would address factors affecting local stream health vs downstream waters</li> </ul>	<ul style="list-style-type: none"> <li>Baywide and stream metrics other than biological indices, such as the Chessie BIBI, to assess physical and chemical health and functions of streams</li> </ul>	Definition of stream health and function to support stream restoration efforts implemented to support of TMDL (Bay health) and local stream health improvements
f. Develop metrics/composite indices from routinely collected, non-biological data to measure changes in stream function to assess regional improvement	<ul style="list-style-type: none"> <li>Limited nutrient and organic matter processing</li> <li>Excessive sediment (erosive, legacy sediment)</li> <li>Excessive nutrient loading to streams</li> <li>Alteration in channel forms and function resulting in instability/disequilibrium</li> <li>Flow dynamics</li> </ul>	<ul style="list-style-type: none"> <li>Benthic macroinvertebrate data from enough streams with enough frequency to track progress over time. Chessie BIBI provides limited capacity for annual tracking, trend analysis less than 5-7 yrs.</li> <li>Identification of priority stressors that affect local stream health and appropriate management actions that will result in functional lift</li> </ul>	<p>Linear feet restored stream length benefited</p> <p>Length of stream corridor which is weighted by overall uplift</p> <p>Reduction <del>in</del> biological impaired 303d streams</p> <p>Pounds of sediment and nutrients removed from implemented WIP stream restoration projects.</p>

Removal/loss of forested riparian area by landowners and excessive sediment and nutrients in-stream would be two priority factors to address</li> </ul>	<ul style="list-style-type: none"> <li>Targeting procedures for cost-effective restoration actions and design approaches that will achieve both water quality and biological functional improvement</li> </ul>	

## X. Biennial Workplan

Biennial workplans for each management strategy will be developed by December 2015. It will include the following information:

- Each key action
- Timeline for the action
- Expected outcome
- Partners responsible for each action

- Estimated resources
