

Tracking Status and Trends in Seven Key Indicators of River and Stream Condition in the Chesapeake Bay Watershed

Presenters: Rosemary M. Fanelli and Lindsey J. Boyle

Chesapeake Bay Nontidal Network: All Stations

Chesapeake Bay Nontidal Network:

- Collaborative effort between the USGS, EPA, bay States, District of Columbia, and the Susquehanna River Basin Commission
- At 123 stations across the watershed, water quality data is assembled to estimate nutrient and sediment loads (mass passing a gaged nontidal location per unit time) and trends in loads over time
- Consistent standardized methods for data collection and trend analysis

The United States Geological Survey launched an initiative tracking the status of and trends in seven key indicators of stream health:

Streamflow

Flow of freshwater in streams, which affects salinity, nutrient, sediment, and contaminant levels

Nutrients and Sediment

Nitrogen, phosphorus, and suspended sediment loads, which affect the health of biological aquatic communities

Temperature

Key for regulating rates of metabolic activity of aquatic organisms and stream productivity

Hydromorphology

Interaction of flow, sediment, geomorphology, and vegetation, creating stream forms and habitat supporting diverse biological communities

Toxic contaminants

Presence of chemical pollutants in streams, which results in at least partial impacts to more than 80% of Bay tidal waters

Salinity

An indicator of dissolved ion concentrations in water, an increase in which can harm biological aquatic communities which are adapted to live in freshwater

Biological aquatic communities

Crucial indicators of the ecosystem health that also provide ecosystem services such as recreational fisheries

Nutrients and Sediment

Purpose

Christopher A. Mason and Douglas L. Moyer

- **Observe:**

- Monitor nutrient and sediment conditions at 123 monitoring stations throughout the Chesapeake Bay Watershed Nontidal Network (NTN).

- **Compute:**

- Compute loads, and trends in flow-normalized loads, every year at the nine River Input Monitoring locations and every two years at the 123-site NTN.

Nutrients and Sediment

Data/Site Criteria

- **Streamflow:**

- USGS National Water Information System (NWIS) daily-value (DV) data from 70-89 gaged sites with complete years of continuous streamflow record from October 1, 1984 to September 30, 2020.

- **Total Nitrogen:**

- Discrete field sampling from 89 sites. At least 20 samples per year, with at least 8 high-flow targeted samples. All results are lab-derived.

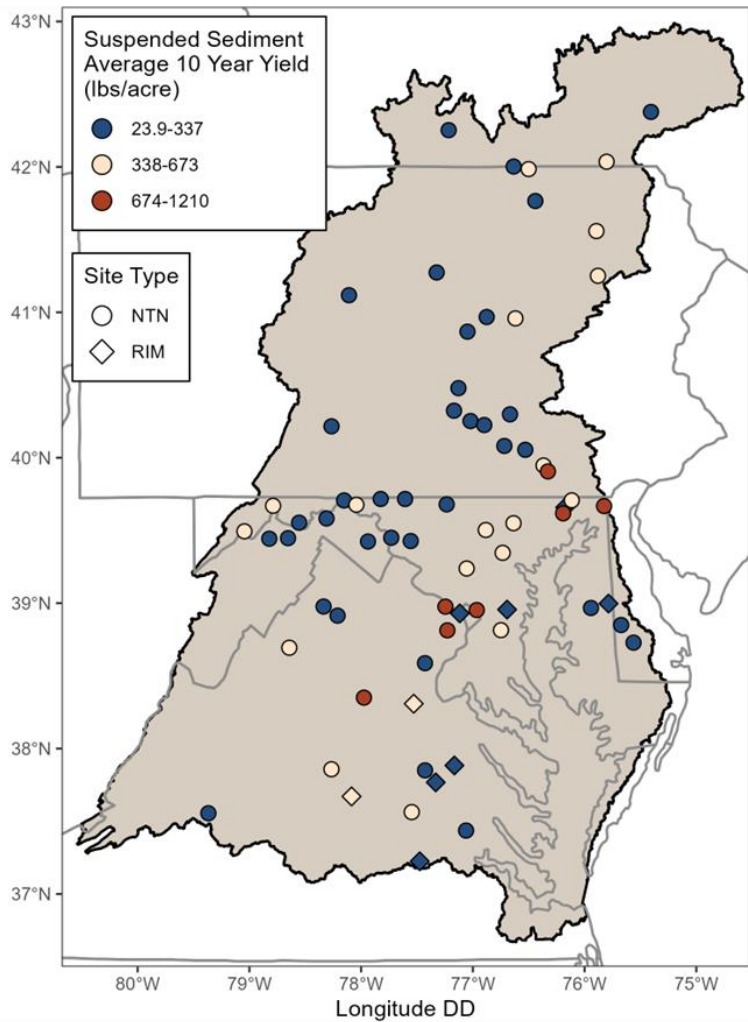

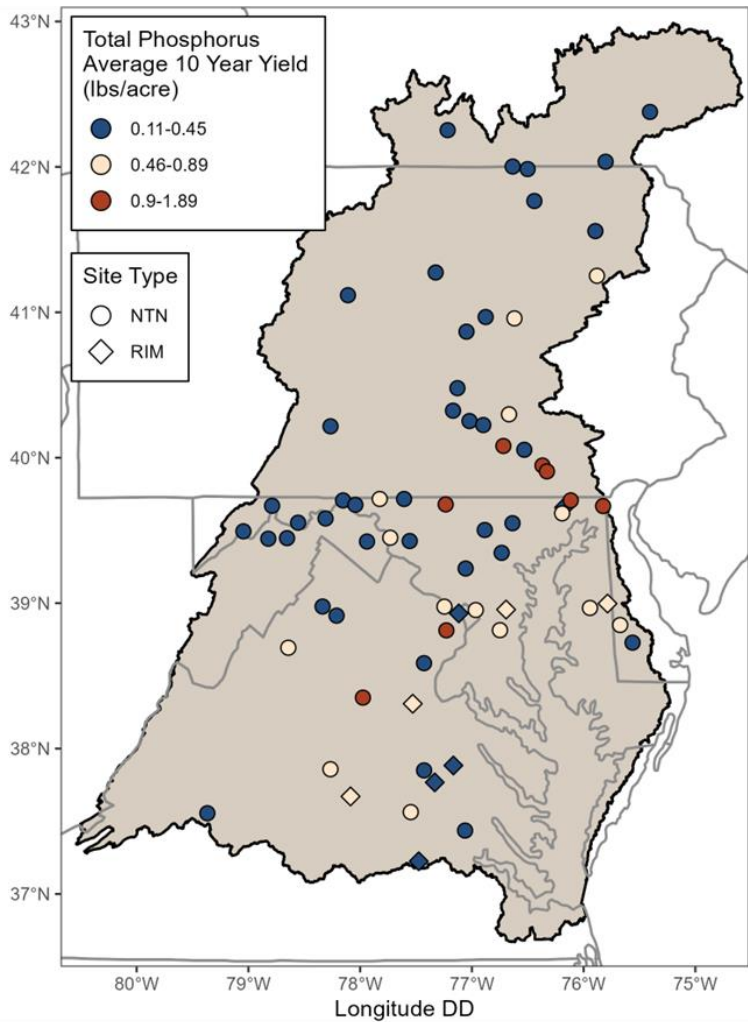

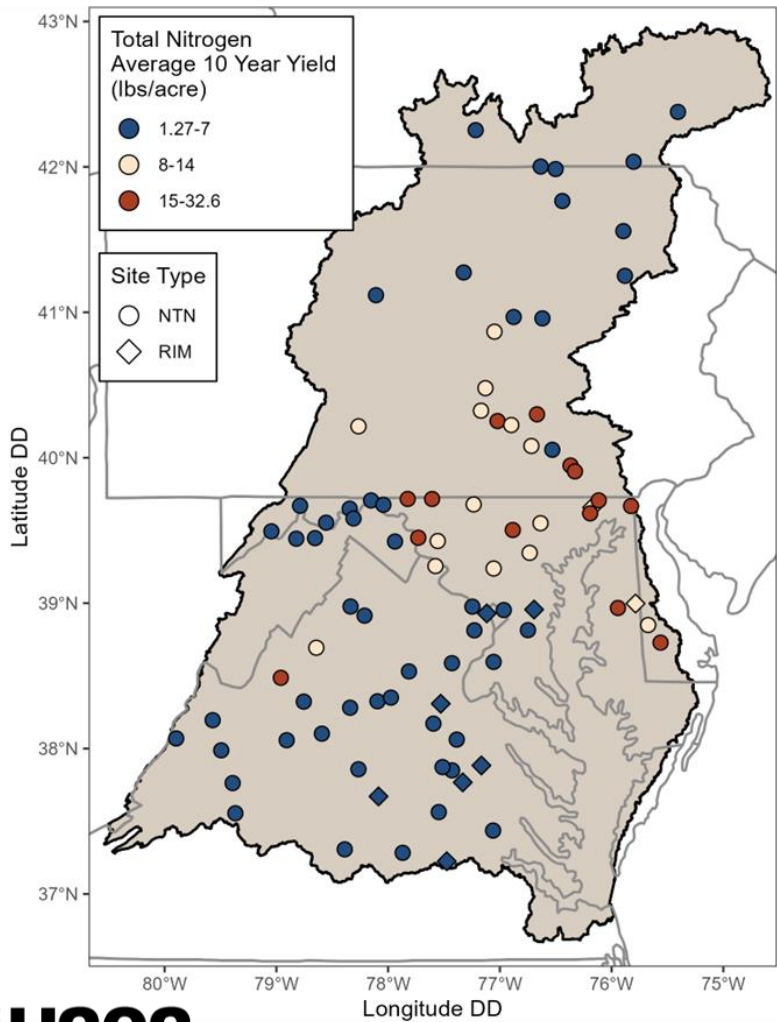

- **Total Phosphorus:**

- Discrete field sampling from 70 sites. At least 20 samples per year, with at least 8 high-flow targeted samples. All results are lab-derived.

- **Suspended Sediment:**

- Discrete field sampling from 70 sites. At least 20 samples per year, with at least 8 high-flow targeted samples. All results are lab-derived.

RISING WATER TEMPERATURES IN CHESAPEAKE BAY AND WATERSHED

Management Responses to Ecological Impacts

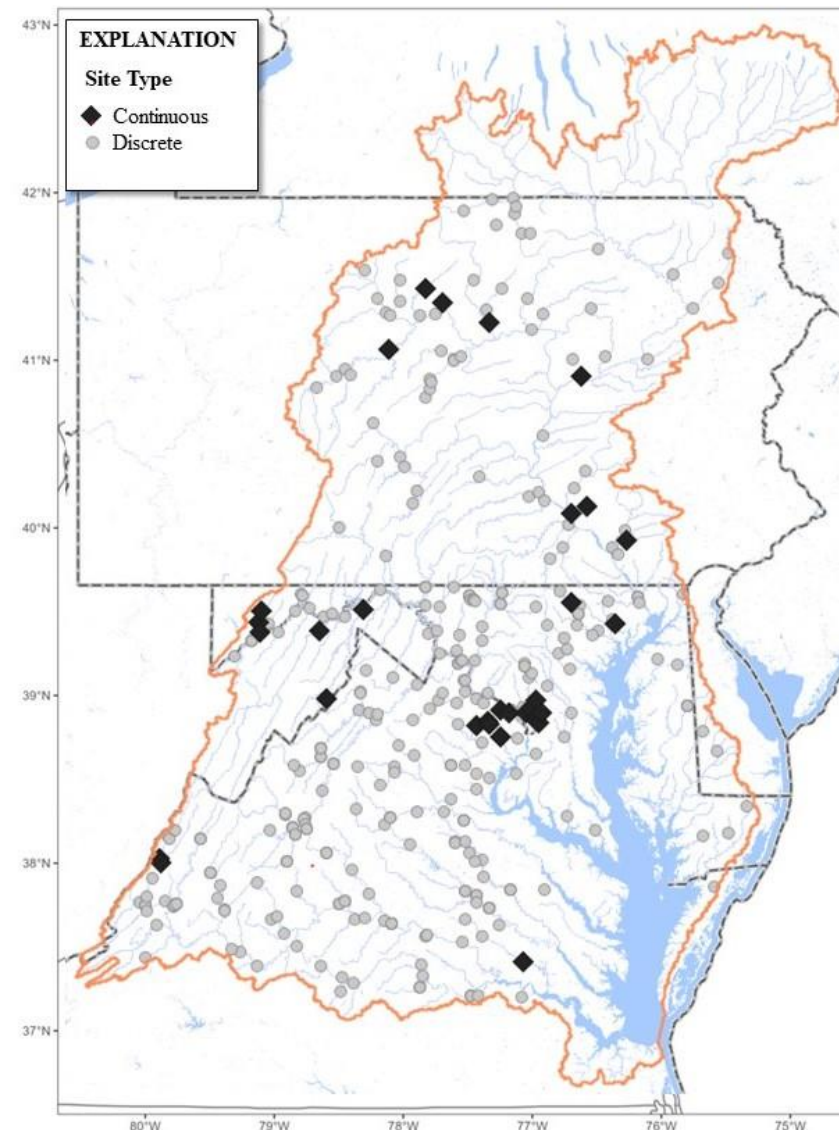

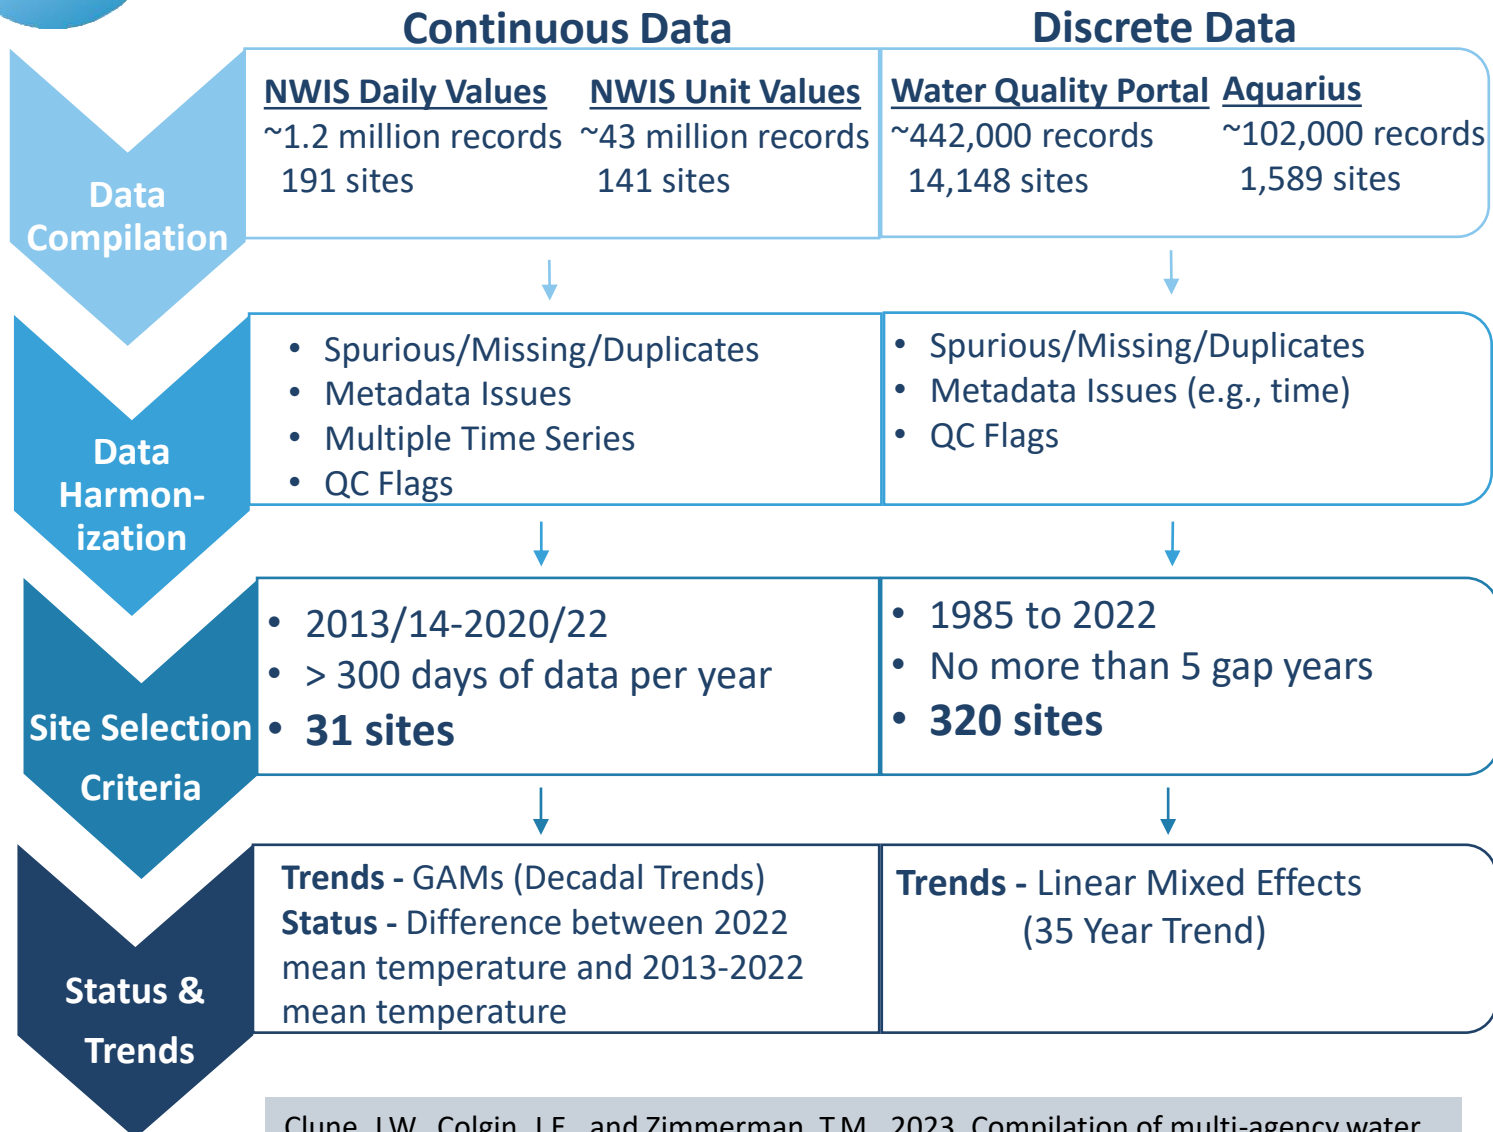

Batiuk et al., 2023

Stream Temperature

Data/Site Criteria

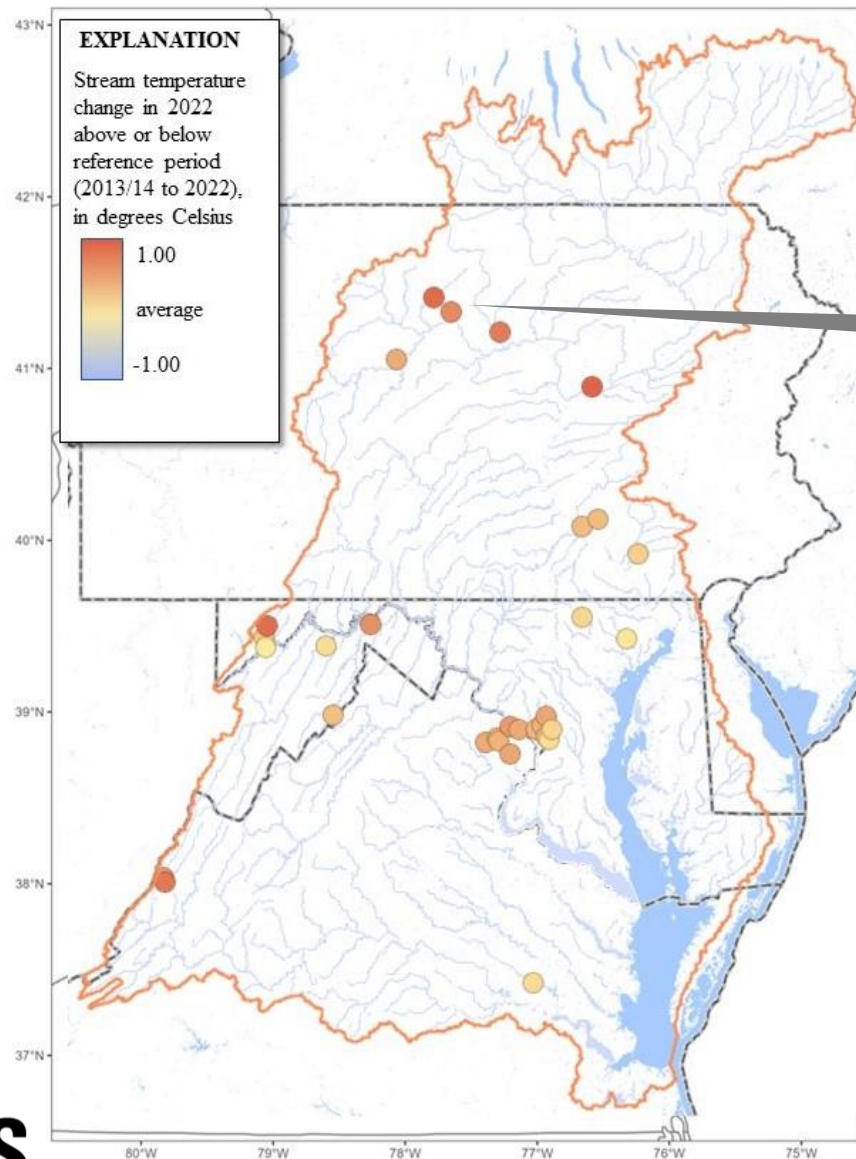

Preliminary data, not for citation or distribution

Stream Temperature

Status

The 2022 water year was the second warmest year for stream temperature on average for **continuous** sites with a 9- or 10-year period of record (2013/2014 to 2022).

Preliminary data, not for citation or distribution

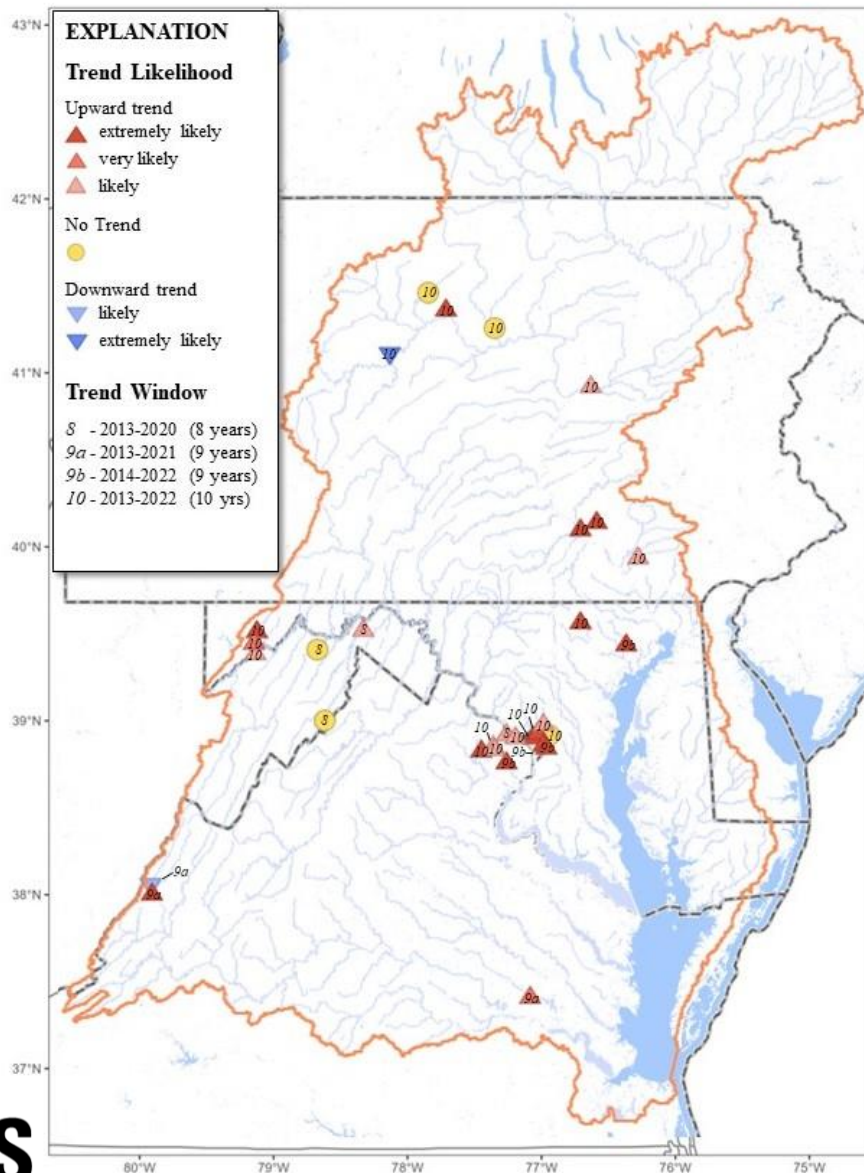

USGS 01545600

The seasonal fluctuation in stream temperature represents a substantial fraction of the annual variability

Stream Temperature

Trends

Increasing trends (0.19 to 1.09 degrees Celsius over period of record) in stream temperature were likely to extremely likely for 79% of the individual **continuous** sites across the Chesapeake Bay watershed, with only two sites indicating downward trends.

Additionally, significant warming trends were apparent across the Chesapeake Bay watershed when grouping **discrete** sites

Stream Salinity

Rosemary M. Fanelli and Kaitlyn E. M. Elliott

Purpose

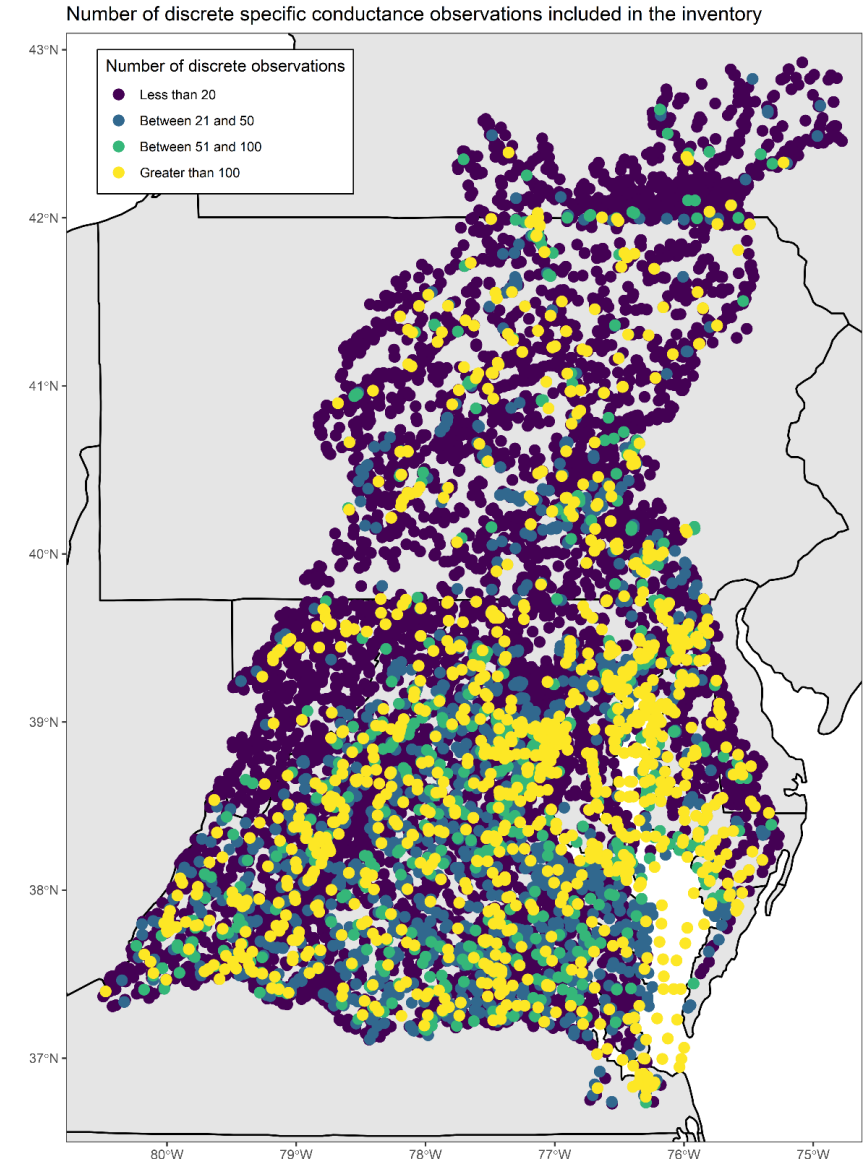

Stream Salinity

Data/Site Criteria

- Retrieved SC data from National Water Quality Portal and USGS NWIS
- 1.2+ million discrete obs at 16,900+ sites
- Date range: 1980-2022
- Dataset clean up and unit harmonization
 - QA/QC samples removed
 - Surface water samples retained
 - Units harmonized to $\mu\text{S}/\text{cm}$
 - Database screened for duplicate entries
- Retained sites that had at least 1 sample per season per year and computed median annual SC as status metric
 - Removed sites with tidal influence

Fanelli, R.M., Sekellick, A.J., and Hamilton, W.B., 2023, Compilation of multi-agency specific conductance observations for streams within the Chesapeake Bay watershed, U.S. Geological Survey data release, <https://doi.org/10.5066/P98O2HQJ>.

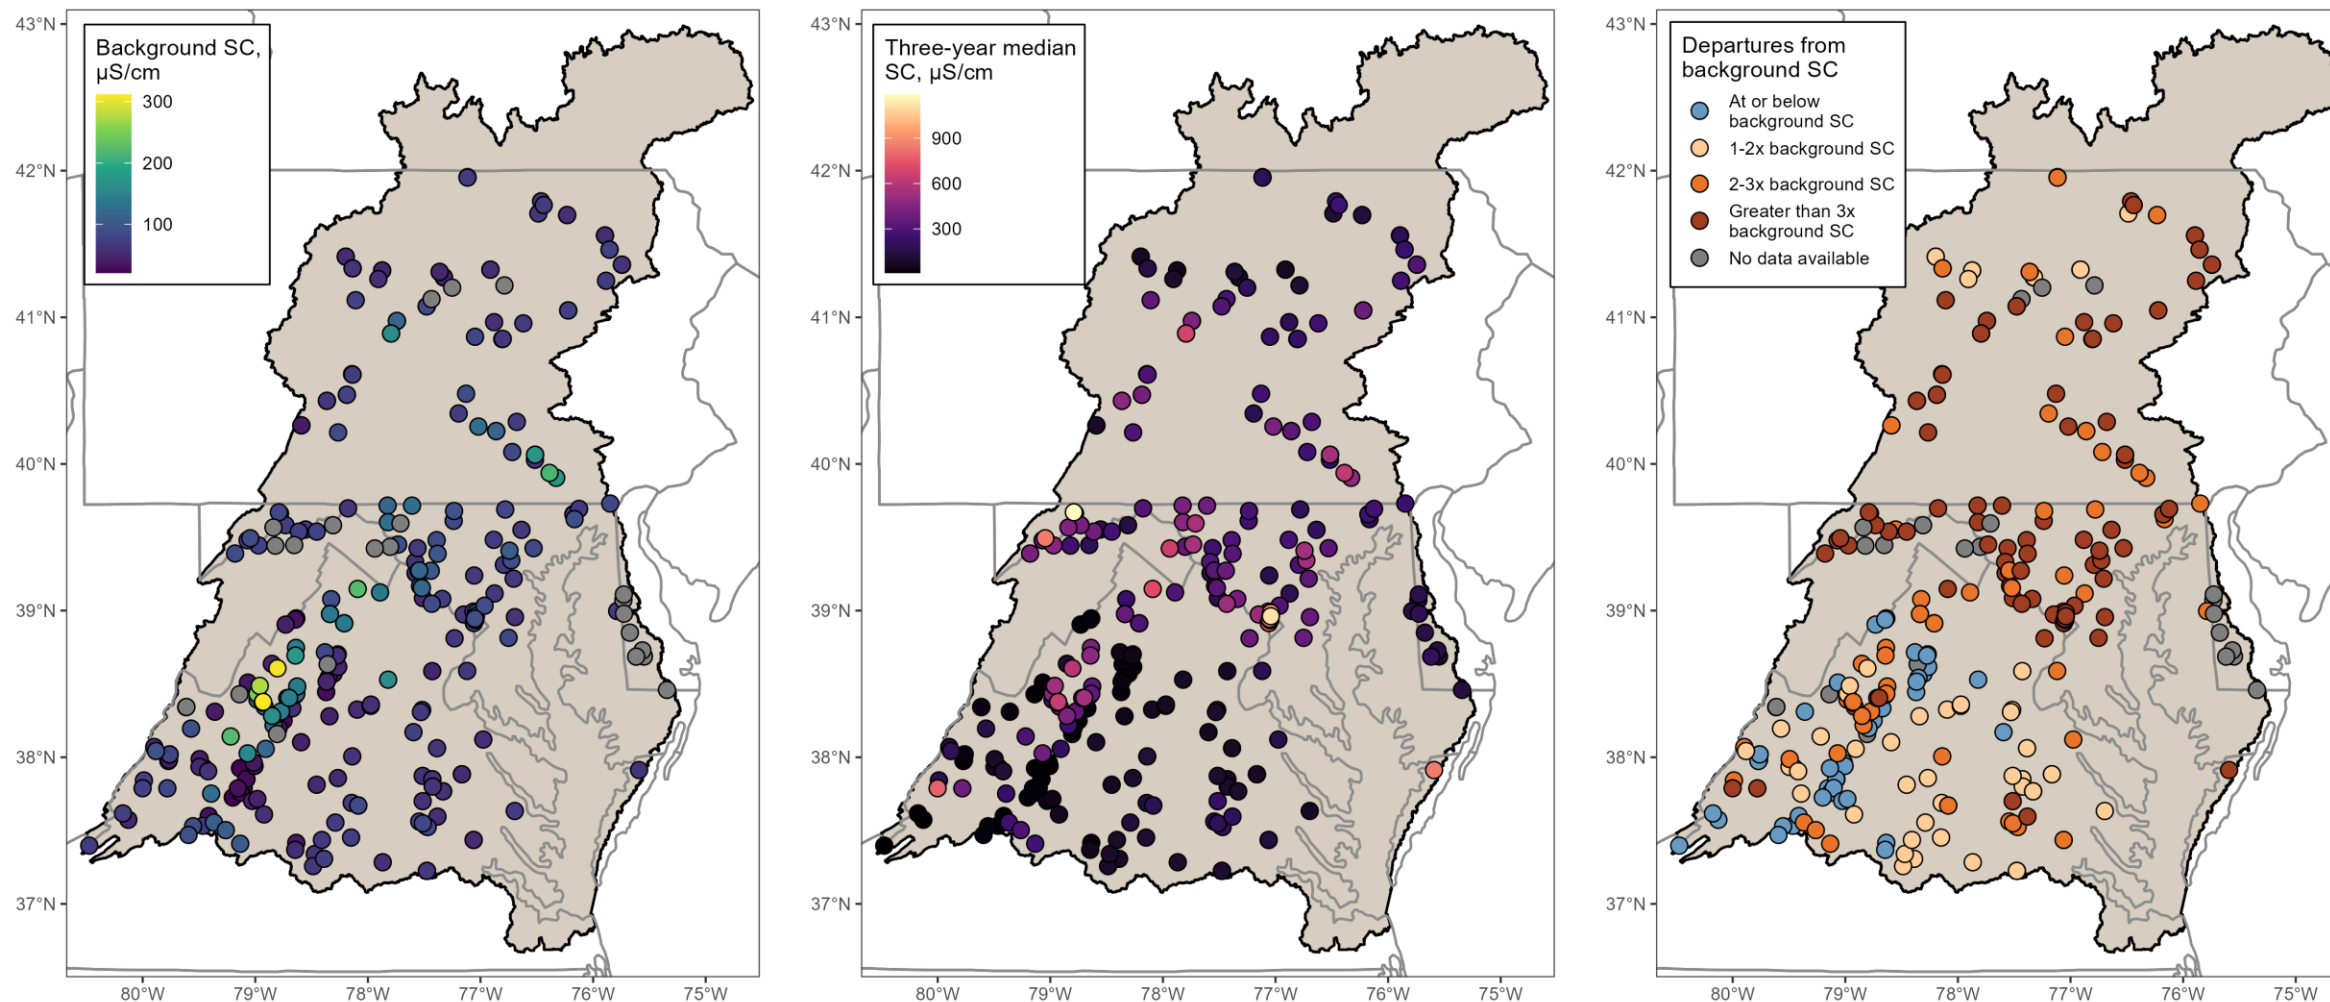

Stream Salinity

Status

3-year median SC for years 2015-2017 compared to SC background dataset

Stream Salinity

Trends

- SC trend time period: 2008-2017
- Approach 1: WRTDS
 - Accounts for interannual flow variability
 - Requires discharge record
 - SC data criteria: three samples per season for each of the 10 years in trend period
 - 35 sites qualified for WRTDS
- Approach 2: Seasonal Mann-Kendall
 - Does not require streamflow records
 - SC data criteria: one sample per season for each of the 10 years in trend period
 - 278 sites qualified for SMK
 - Defined criteria for characterizing trend significance and uncertainty

Example SC trends by season at a single site

Stream Salinity

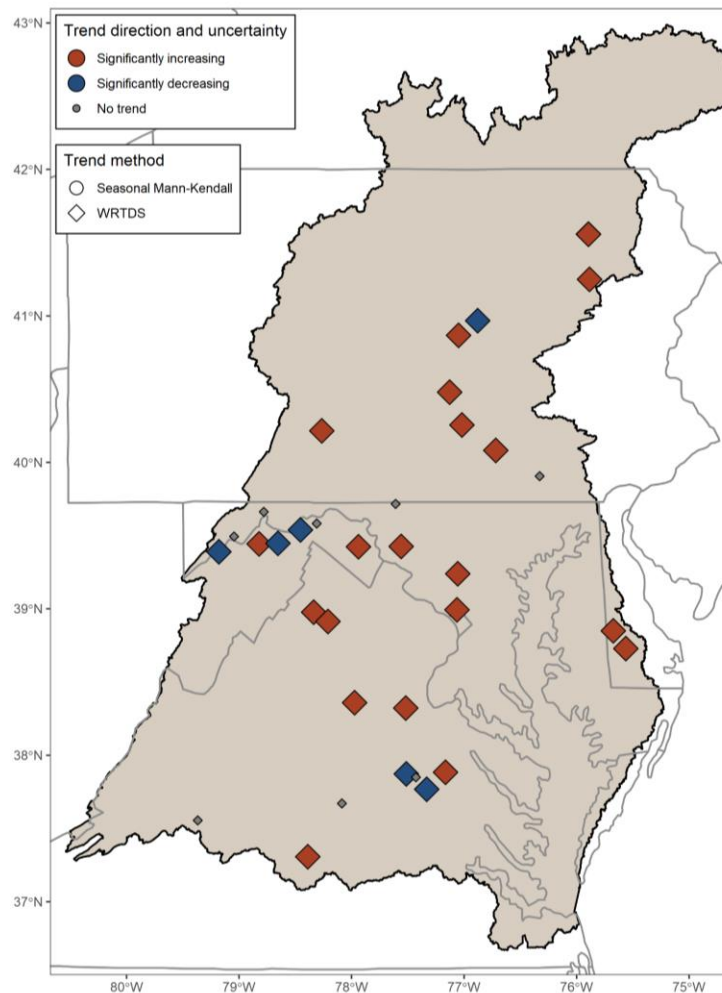

Trends

WRTDS - Accounts for interannual flow variability, requires 3 samples per season per year, has fewer qualifying sites

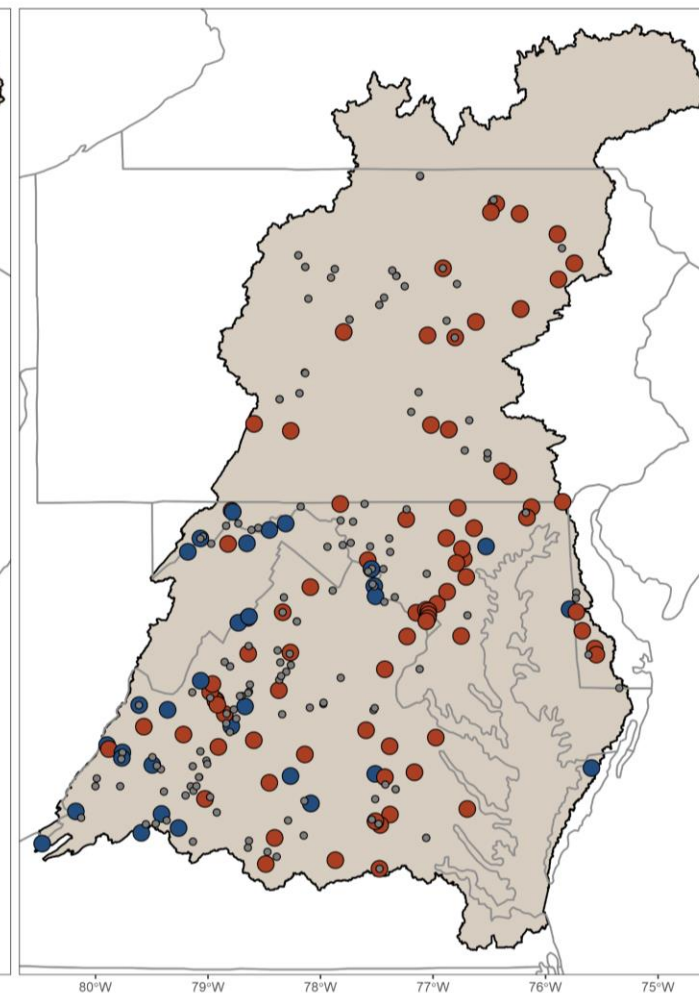

Seasonal Mann-Kendall – Does not account for flow, requires 1 sample per season per year, more qualifying sites

Trend Metric	Percent Increasing Trend	Percent Decreasing Trend	Percent No Trend
WRTDS (n = 35)	60	18	23
SMK (n = 278)	33	12	55

WRTDS Trends

SMK Trends

Toxic Contaminants

Purpose

Trevor P. Needham, Ellie P. Foss, Emily H. Majcher

How much of the Chesapeake Bay is impacted by chemical contaminants?

Data from the U.S. Environmental Protection Agency

According to data submitted to the U.S. Environmental Protection Agency in 2018, 84 percent of the Chesapeake Bay's tidal segments are partially or fully impaired by toxic contaminants.

While chemical contamination is often seen as a localized problem occurring in "hot spots" or "regions of concern," metals, polychlorinated biphenyls (PCBs) and priority organics exceed water quality criteria in at least part of all of the tidal tributaries that deliver water to the main stem of the Bay. A technical report shows PCBs and mercury are particularly problematic in the region, and are considered widespread in severity and extent

Pesticides
PCBs
Mercury

Toxic Contaminants

Data

Summary of toxics database developed by media and contaminant:

	Water	Biological	Sediment	Solids	Soil
Pesticide	200,804	5,552	6,465	2,514	0
PCB	1,614	9,001	2,827	55	25
Hg	2,484	7,767	1,942	13	45

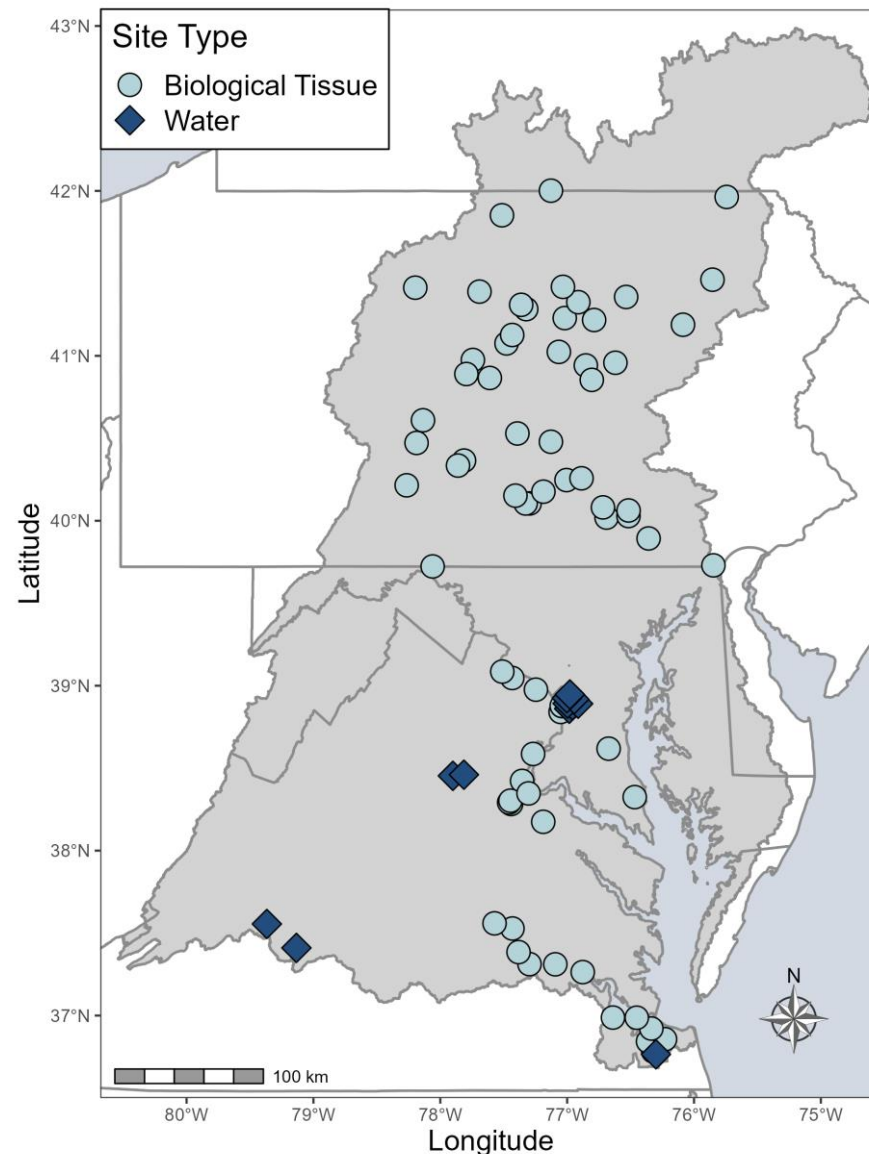

- Toxic contaminant database developed for polychlorinated biphenyls (PCB), mercury (Hg), and pesticides published in Science Base (Banks and others, 2022)
- Records compiled from DE, PA, MD, NY, VA, WV, DC, NWIS, and WQP from 1938 to 2019.
- Data availability by contaminant and media was driven by total maximum daily load enforcement and exposure pathways (for example PCBs in fish)

Toxic Contaminants

Site Criteria

- No sites with enough consistent, repeat samples in the same sampling medium. Trend analysis currently not possible.
- Identified 89 PCB sites where trend analysis might be possible if monitoring continues. Site criteria:
 - Temporal Duration: Sites with 3 or more sampling points for the same media over a 5-year span or greater.
 - Recency: Sites need to have been sampled between 2014 and 2020 (end of data record).
 - Method Compatibility: PCB analysis must be by a method that reports total PCB concentration or individual PCB congeners; Aroclor methods were excluded.
 - Media Compatibility: Only similar media can be compared for trend analysis. The selection was limited to solids, water samples, fish of the same species, or different fish species with a reported lipid content as these media types contained enough data for within-media trend comparisons.

Preliminary data, not for citation or distribution

Streamflow

Samuel H. Austin

Purpose

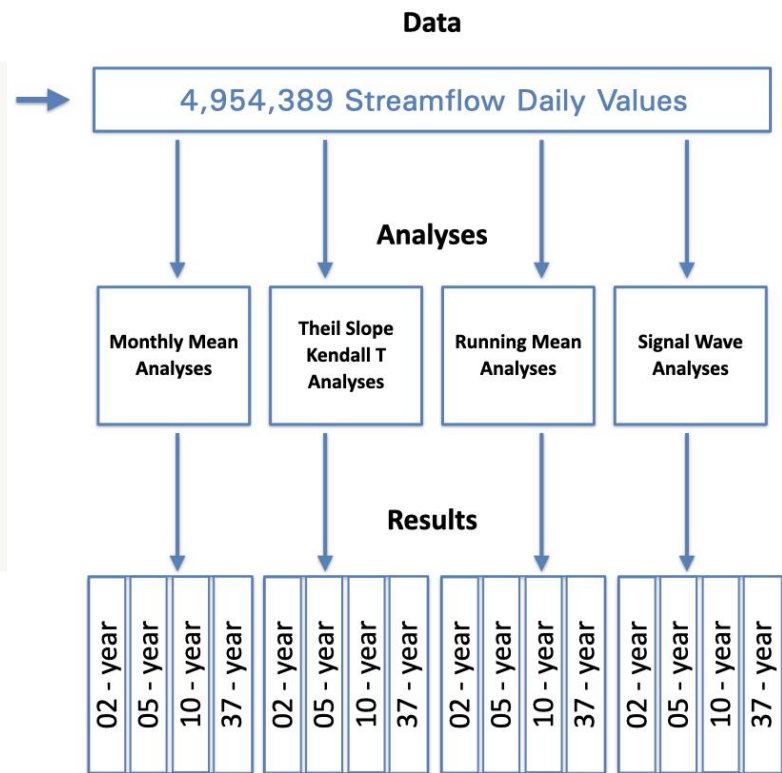

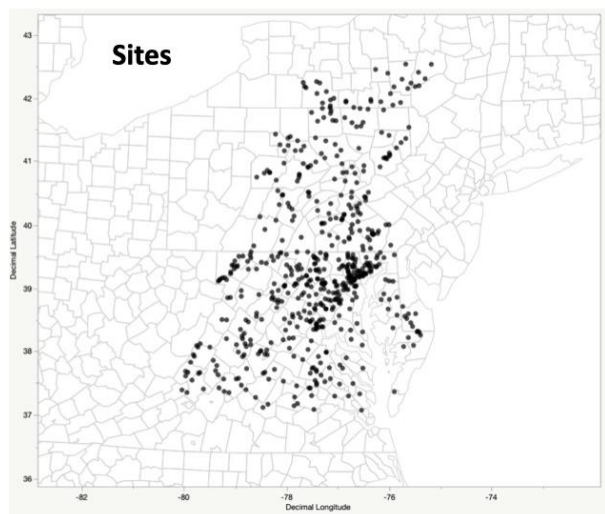

Streamflow

Data/Site Criteria

- USGS National Water Information System (NWIS) daily-value (DV) data from 417 gaged sites with at least 10 complete years of continuous streamflow record within the October 1, 1984 to September 30, 2022 interval

- Four methods of evaluating streamflow were calculated to provide maximum relevance and flexibility when addressing policy needs and questions specified within shorter-term and longer-term time intervals-of-interest
- Status = mean yearly flow of all sites relative to all water years in period of record (1986-2022)
- Trends = Theil-Sen regression at 2, 5, 10 and 36 year intervals

Streamflow

Status

- Status = mean yearly streamflow of all sites
- 2022 ranked 12th lowest mean annual flow out of the past 37 water years
- 2002 was the lowest water year and 1996 was the highest water year

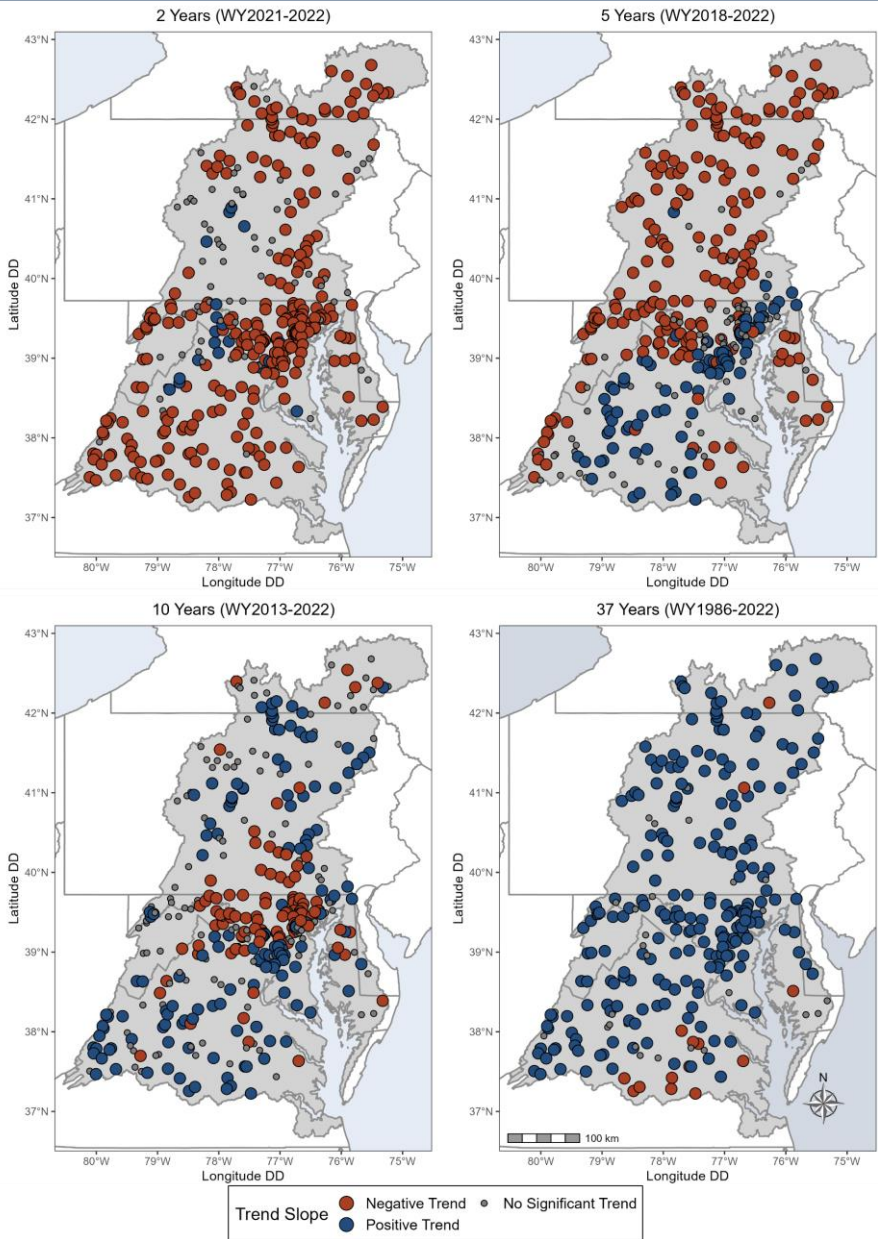

Streamflow

Trends

Trends in short-term (2-5 years) and long-term (10-37 years) streamflow

Trend Intervals	Percent Negative Trend	Percent Positive Trend	Percent No Trend
2 Years (n=378)	73	6	21
5 Years (n=377)	54	23	23
10 Years (n=372)	27	39	34
37 Years (n=273)	5	83	12

Hydromorphology

Purpose

Matthew J. Cashman, Coral M. Howe, Joshua J. Thompson, Marina Metes, Zachary Clifton

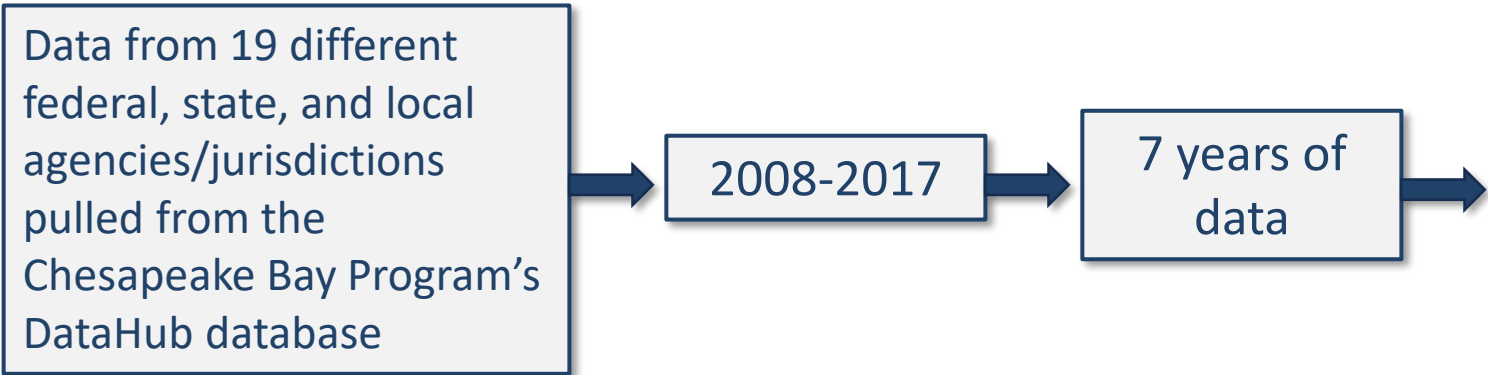

- Sediment & physical habitat degradation have been identified as a leading cause of local ecological impairment across the Chesapeake Bay watershed (CBW)(Fanelli & others, 2022)
- Degraded bed conditions often regulatorily linked to sediment, but sediment is only one of several possible factors of degraded bed conditions
- Two approaches to evaluating these trends in these factors within the CBW:
 1. Rapid Habitat Assessments across multiple jurisdictions
 2. Specific Gage Analysis, i.e. trends in channel dimensions and hydraulics at USGS streamgages

Image credit: Marina Metes

Rapid Habitat Assessment:

- Field methods for measuring hydromorphic & physical habitat conditions at a site
- Intended to be a **quick, visually-qualitative ranking** (0=poor, 20=optimal) of conditions at a **meso- and microhabitat spatial scale**

METRIC SHORT NAME	METRIC LONG NAME	RANGE	QUALIFYING SITES (N)
BANKS	Bank Stability	0-20	83
BANKV	Bank Vegetative Protection	0-20	83
CH_ALT	Channel Alteration	0-20	84
EMBED	Embeddedness	0-20	101
EPI_SUB	Epifaunal Substrate/Available Cover	0-20	93
FLOW	Channel Streamflow Status	0-20	84
RIFF	Frequency of Riffles (or Bends)	0-20	51
SED	Sediment Deposition	0-20	84
VEL_D	Velocity/Depth Combinations	0-20	55

Hydromorphology (Rapid Habitat)

Status

- Average metric value for the most recent three years of data per site
- Metrics averaged from 12.0 to 16.4
 - Lowest average = Channel Embeddedness
 - Highest average = Channel Alteration
- Lower scores generally clustered near urban centers and on the Delmarva Peninsula

Hydromorphology (Rapid Habitat)

Trends

- Generalize additive model results 2008-2017
- Among all sites and metrics, 9% had strong significant trends
- Of these trends, 77% indicated **degrading conditions**
- Overall **trend** for all metrics was an avg of **-0.37pts/year**
- Significant changes scattered throughout watershed, but the most notable changes were clustered near urban centers

Negative Slope= Degrading Positive Slope = Improving

Hydromorphology (Specific Gage) Data/Site Criteria

Specific Gage Analysis:

- Uses routine streamflow measurements collected at USGS streamgages to document changes to channel dimensions and hydraulics, i.e., channel evolution
- Three metrics; Bed Elevation, Channel Area and Channel Velocity, selected for analysis

Streamgage data for all watershed gages queried from the National Water Information System

at least 10 years of continuous streamflow and stage data

342 USGS gages qualified for at least a 10-yr trend analysis

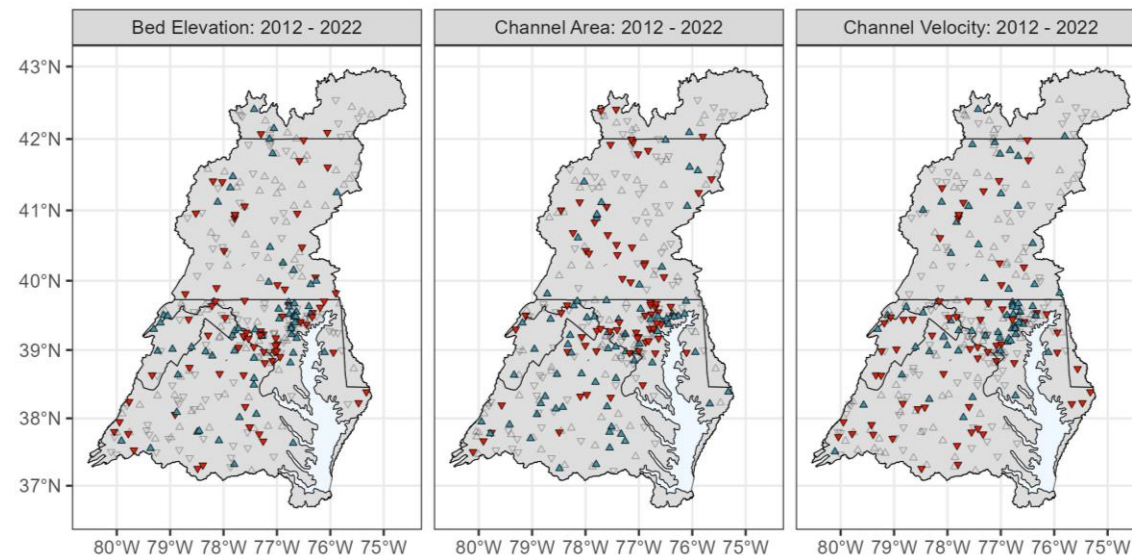

Hydromorphology (Specific Gage)

Trends

- Between 36%-51% of trends analyzed for each time interval (10-, 25-, 50-, 75-yrs) were significant ($p\text{-value} \leq 0.05$). 75-yr intervals had the most significant trends.
- Channel Velocity and Channel Area had fewest significant trends (41%), Bed Elevation the most (47%)
- Bed Elevation and Channel Velocity more likely to be decreasing through time, Channel Area more likely to be increasing through time

10-Year Trends in Stream Channel Metrics

50-Year Trends in Stream Channel Metrics

▼ Decreasing Not Significant ▼ Decreasing Significant ▲ Increasing Not Significant ▲ Increasing Significant

Biological Assemblages

Purpose

Biological Assemblages

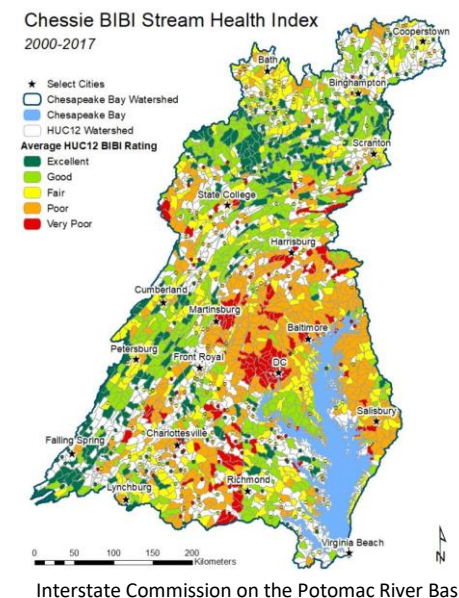

Data/Site Criteria

Multi-Metric Index – aggregates multiple biological assemblages metrics into a single value indicating overall biological condition

- Macroinvertebrates = Chessie BIBI (Interstate Commission on the Potomac River Basin)
- Fish = EPA MMI

Assemblage Sensitivity – metric quantifying the proportion of species or individuals within a population that are highly sensitive to disturbance

- Macroinvertebrates = % Ephemeroptera, Plecoptera & Trichoptera
Taxa excluding the tolerant family Hydropsychidae (EPT-H)
- Fish = Percent of non-tolerant individuals

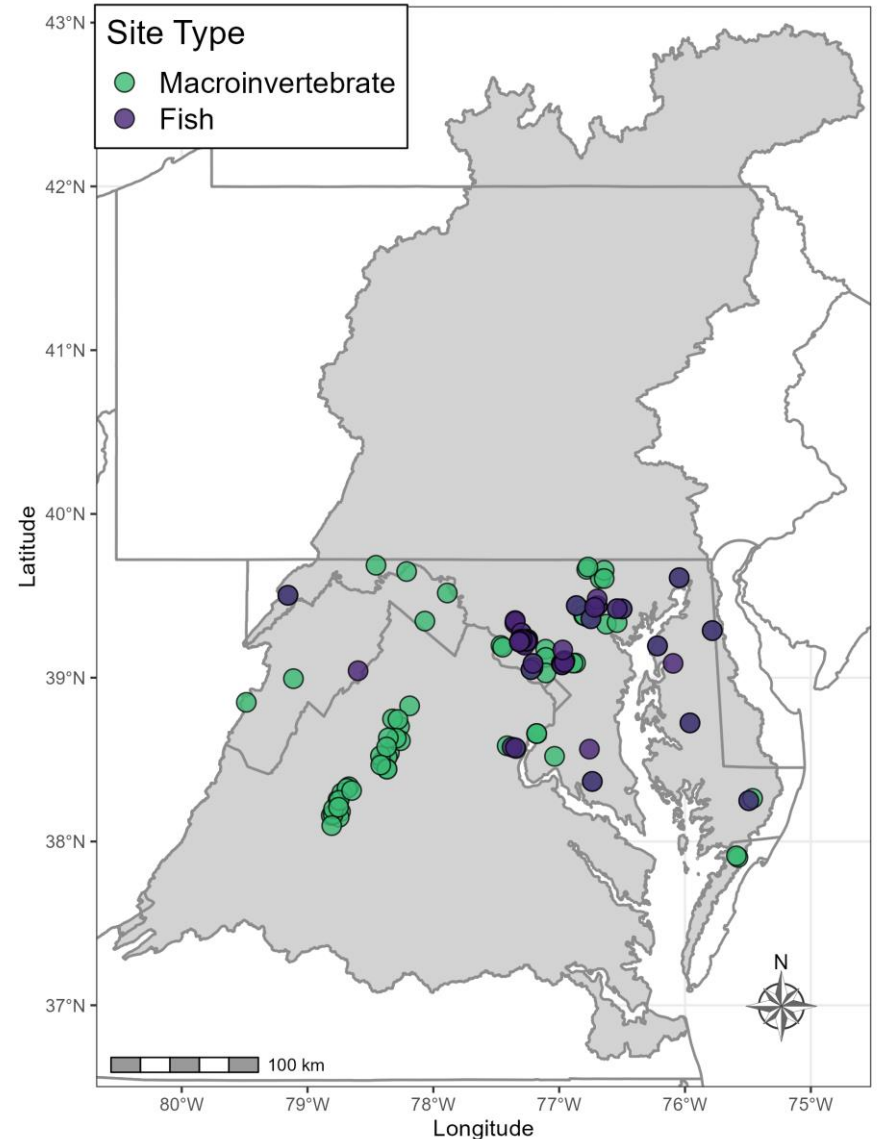

29,009 Macroinvertebrate samples (ICPRB)
12,418 Fish samples (USGS)

2008-2017

7 years of data collected in the same season

	Spring	Summer	Autumn	Total
Macroinvertebrate Sites	93	4	2	<u>99</u>
Fish Sites	0	36	8	<u>44</u>

Sites with ≥7 Data Years in 2008-2017

Preliminary data, not for citation or distribution

Biological Assemblages

Status

Average metric value for the most recent three years of data per site

Macroinvertebrates

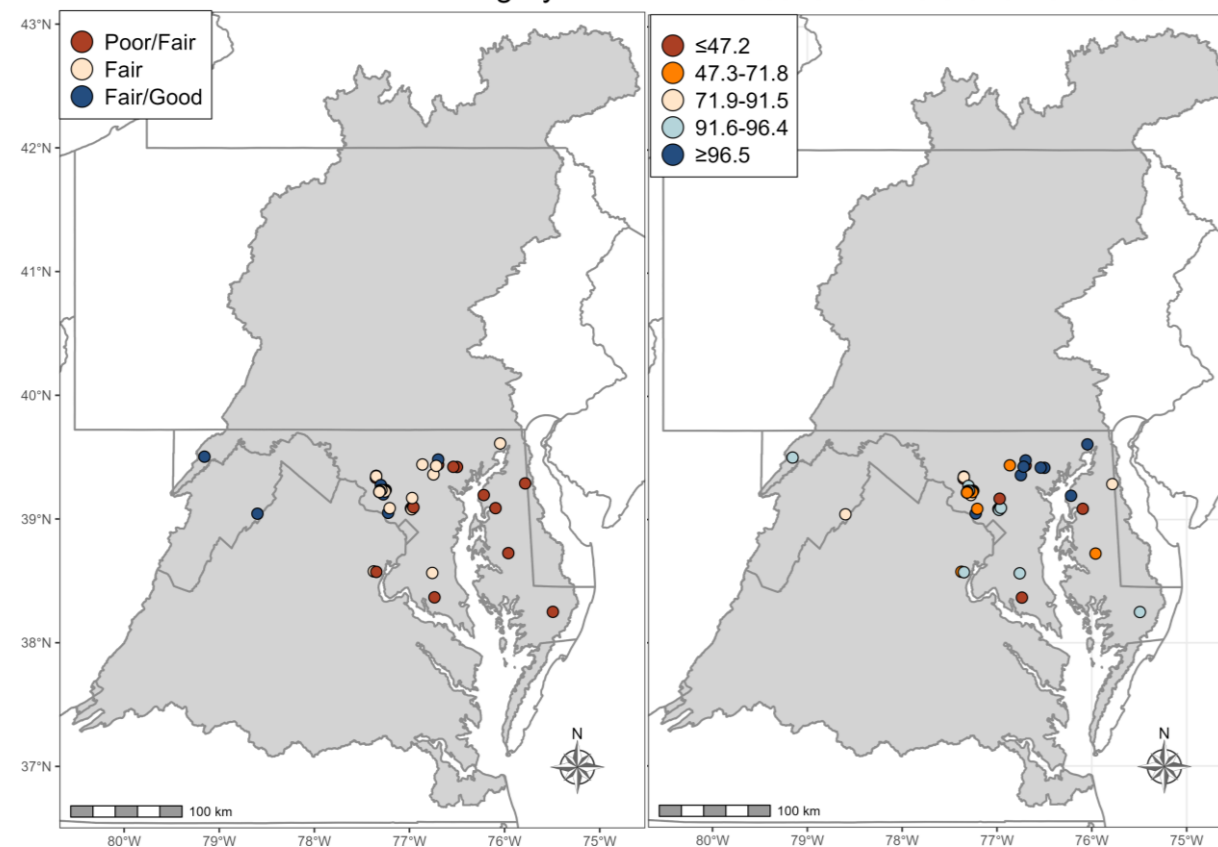

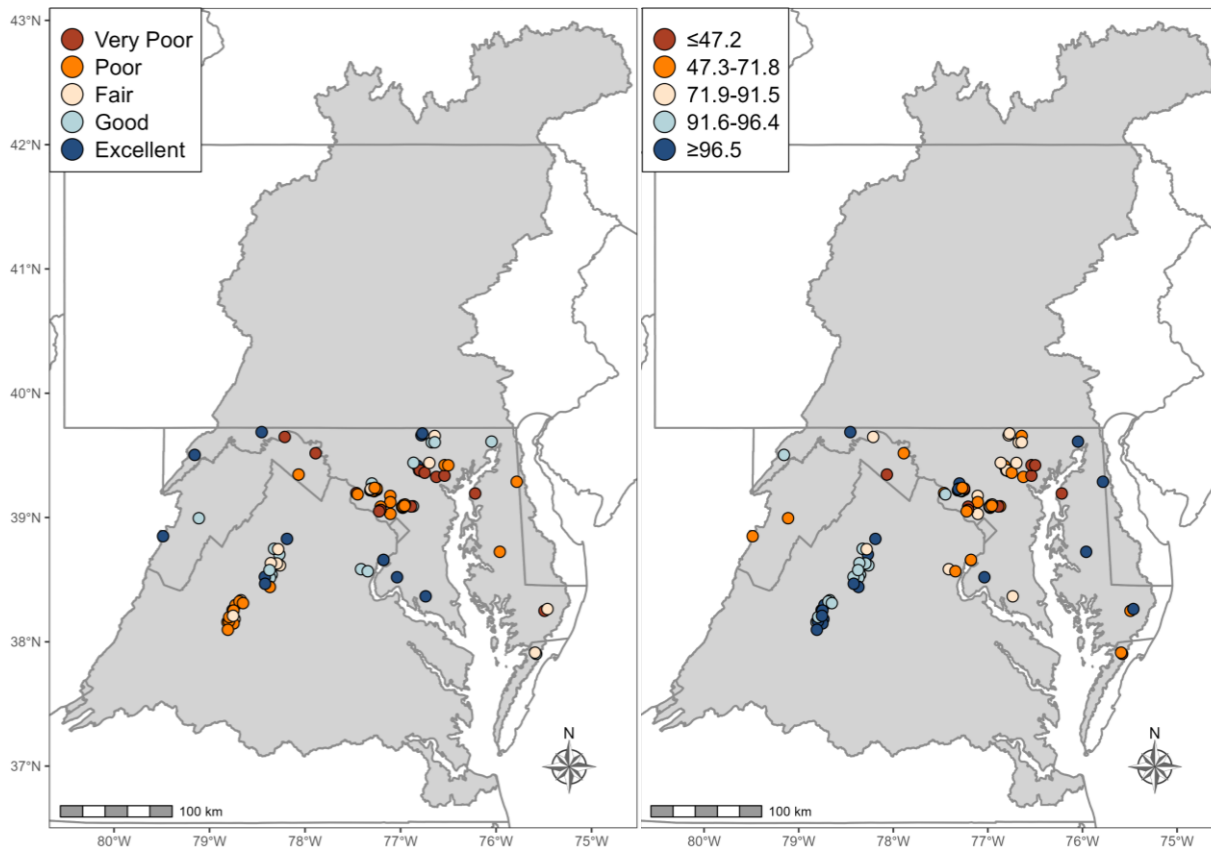

Fish

BIBI Condition Category

Percent EPT-H Taxa

EPA MMI Condition Category

Percent Non-Tolerant Individuals

Biological Assemblages

Trends

Generalize additive model results 2008-2017

	Metric	Percent Increasing Trend	Percent Decreasing Trend	Percent No Trend
Macroinvertebrates	BIBI Score	2	4	94
	Percent EPT-H Taxa	4	8	88
Fish	MMI Score	11	0	89
	Percent Non-Tolerant Individuals	11	14	75

Key Takeaways

Nutrients and Sediment

Largest TN yields near the mouth of the Susquehanna and on the Eastern Shore, TP yields near the mouth of the Susquehanna and suspended sediment yields near mouth of the Potomac. Majority of sites showed **either improving or degrading trends for TN, improving trends for TP and either degrading or no trend for suspended sediment.**

Stream Temperature

The 2022 water year was the **second warmest year** and increasing trends (0.19 to 1.09 C) were likely for 79% of the available continuous sites (2013/2014 to 2022) and **warming trends** were apparent across the Chesapeake Bay watershed when grouping discrete sites.

Salinity

85% of sites had 3-year median SC values **above predicted background SC**. SC was **increasing at 60% of WRTDS trend sites.**

Toxic Contaminants

Differences in sampling medium, sampling frequency and monitoring protocols make trend analysis of toxic contaminants (PCBs, Hg, pesticides) difficult. **Not enough data exists** in the toxic contaminant dataset for trend analysis, but **89 sites** have repeat samples that **may be suitable for future analysis** if monitoring continues.

Streamflow

Annual streamflows into the Chesapeake Bay Watershed during the 2022 water-year were **below average**, ranking 12th of 37 years. Trends show decreasing flows at short (2 or 5 year) timescales but **little change over the full period of record (37 years).**

Hydromorphology

Analysis of field-based Rapid Habitat Assessment data showed **the majority of habitat metrics with significant trends indicate degrading condition.** Specific Gage Analysis captured a pattern of **streams becoming more shallow, and wide with lower channel velocity** over time.

Biological Assemblages

Very few sites had strong directional change in trend window (2008-2017) but significant **trends show more declines than increases in macroinvertebrate and fish sensitive taxa, increases in fish multi metric index scores, and decreases in macroinvertebrate multi metric index scores.** Additional data (currently compiling 2018-2023) may greatly increase spatial and temporal coverage of biological trend sites.

Challenges

	Stream flow	Specific Gage	Nutrients Sediment	Salinity	Temp.	Toxics	Habitat	Macroinverts.	Fish
Streamflow	417	342	115	88	28	13	9	7	0
