Scenario Builder and Watershed Model Plan for the MPA

In preparation for the 2017 Mid-Point Assessment, the CBP Partnership has expressed priorities for the Phase 6 watershed model development which are detailed in documents under the 'Projects and Resources' tab on the Water Quality GIT page. Initial priorities were set in the October 2012 water quality GIT meeting. These priorities have been updated and refined by recommendations from subsequent workshops and CBP meetings. The MPA master schedule lists these priorities in a table format. Additional documents on the web page are specific work plans to accomplish these tasks.

Out of necessity, phase 6 development is occurring along multiple parallel paths. These must eventually meet in a draft phase 6 watershed model and scenario builder that will be ready for full partnership review beginning January 1 2016. These parallel paths encompass all of the CBP priorities.

This document summarizes the priorities and identifies lead researchers for each effort. The descriptions here are brief with links to more detailed workplans.

Efforts

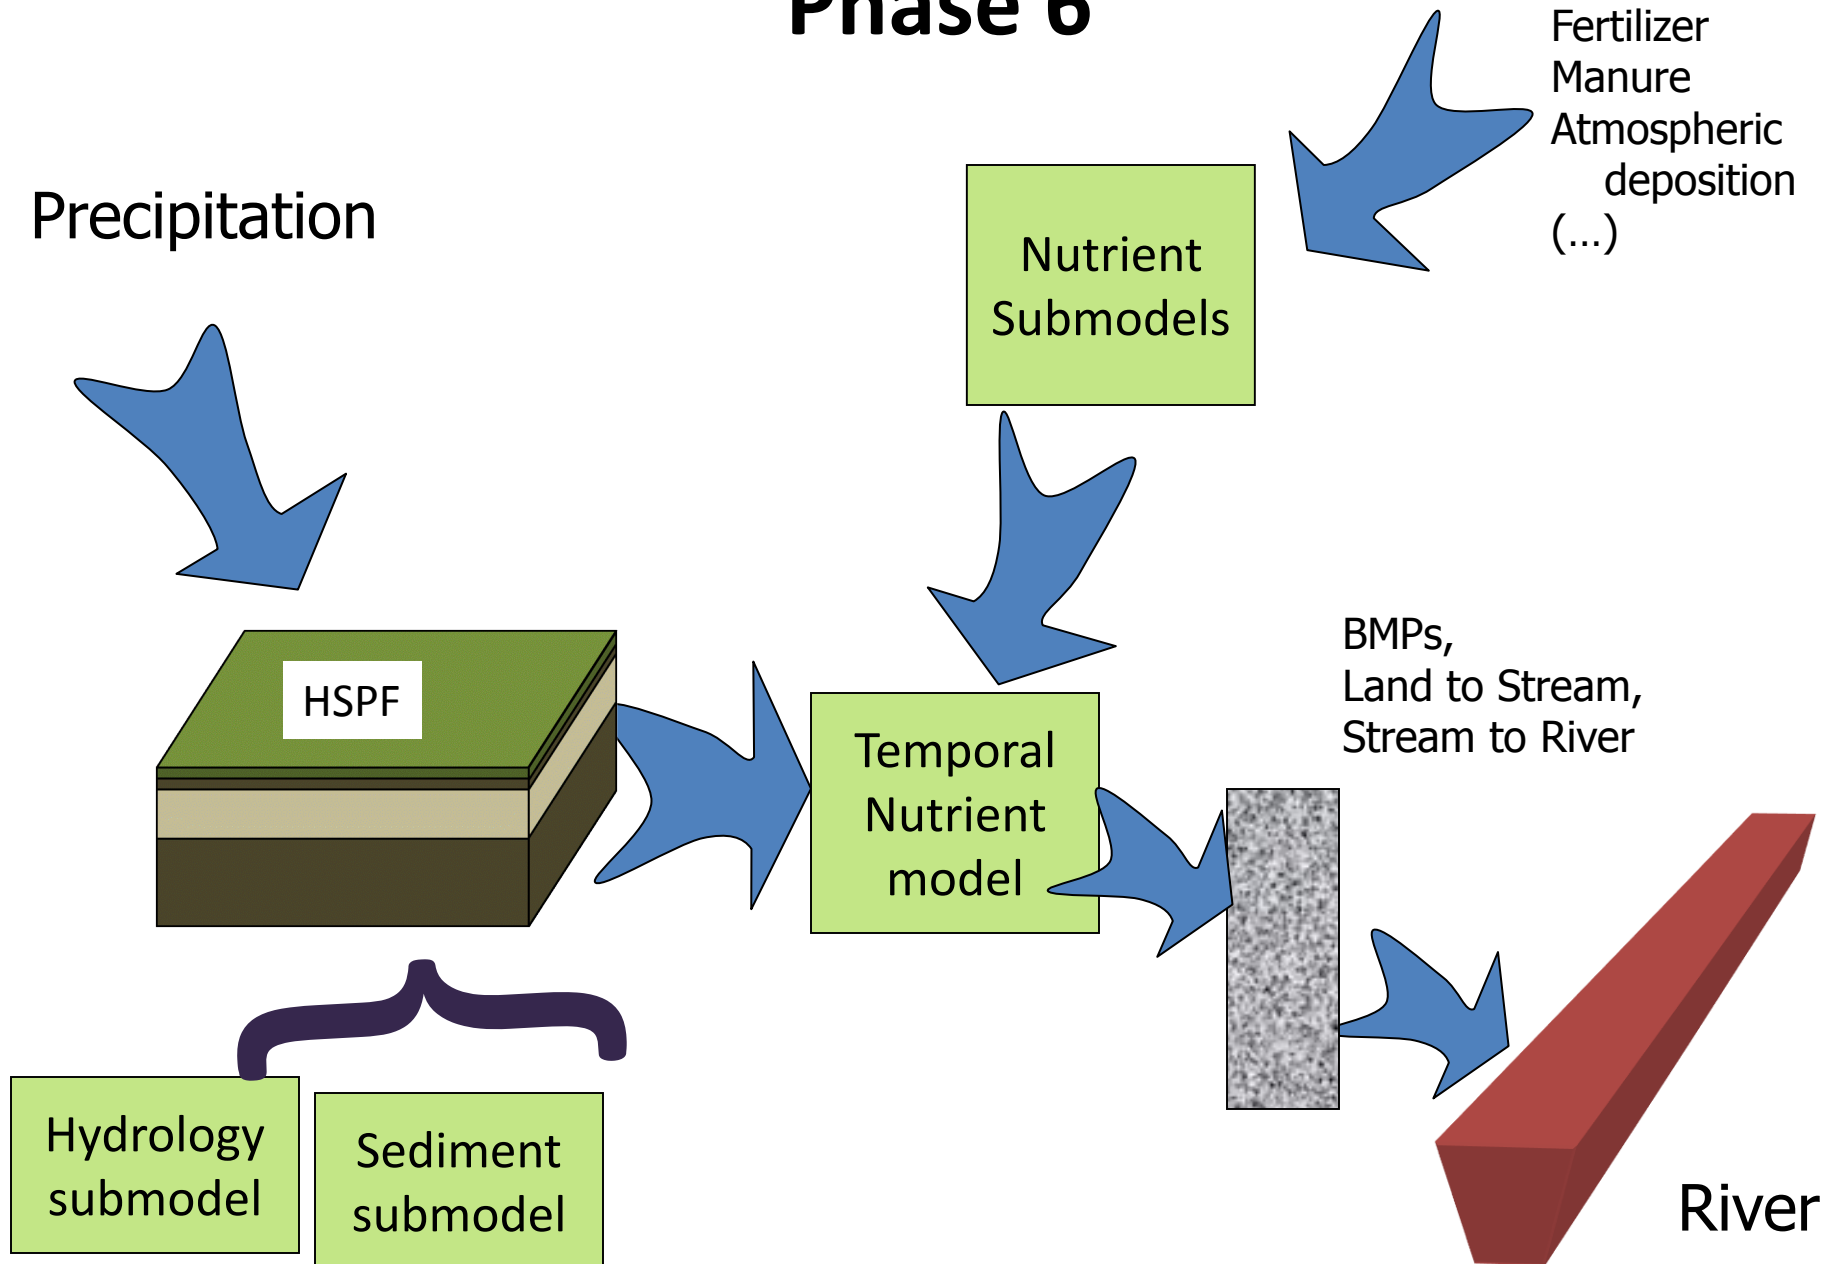

Below are the efforts related to the Scenario Builder and Watershed Model Plan for the Mid-Point Assessment

- [BMP effectiveness](#)
- [BMP Implementation Accounting](#)
- [Fertilizer and Manure Applications](#)
- [Land Use Types and Acreage](#)
- [Land Use Loading Rates](#)
- [Climate Change](#)

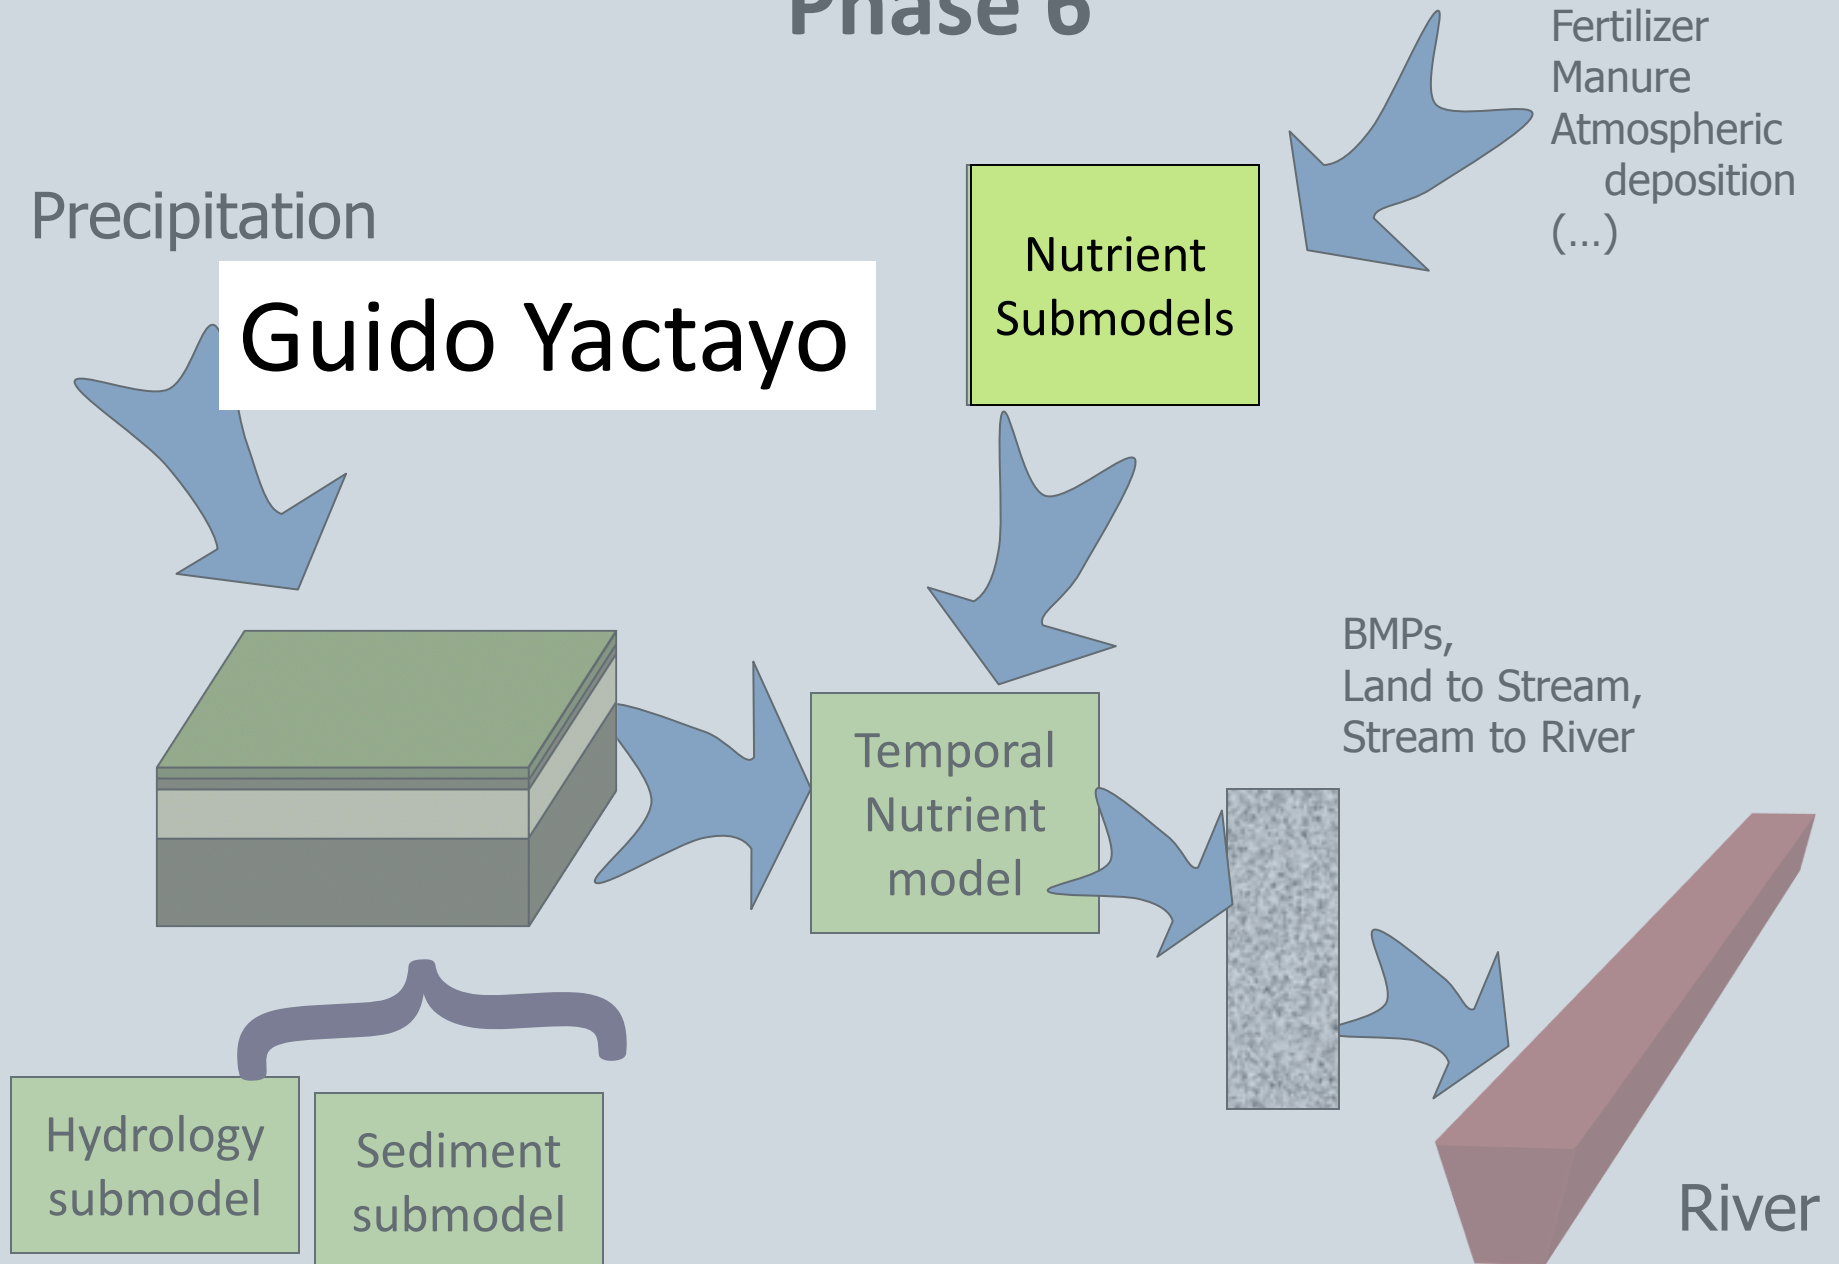

1-Slide Status Report

- Land Use Types and Acreage
- Land Use Loading Rates
- Climate Change
- Scenario Builder Development and Code Versioning
- Watershed Model Development and Code Versioning
- Calibration Methodology
- Sensitivities to inputs
- Fine-scale Processes
- Atmospheric Data
- Groundwater Lag
- Better Representation of Reservoirs

Recommendations for Phase 6- PQUAL Nitrogen Sensitivity

Guido Yactayo – UMCES
gyactayo@chesapeakebay.net

Objectives

- To estimate multiple watershed models sensitivity to nutrient inputs in the Chesapeake Bay
- To develop, review and implement model sensitivities in the phase 6 version of the Chesapeake Bay Watershed model
- To decide on Phase 6-PQUAL nitrogen sensitivities

** The input-output relationship or the effect of changes in nutrient inputs on nutrient export is referred to in this analysis as sensitivity.*

Sensitivities to total nitrogen inputs

- Following STAC recommendations of using multiple models, APEX, SPARROW, and P532-AGCHEM models were included in this analysis.
- The models sensitivities represent the relationship between nutrient predicted yields and input loads for cropland.

Sensitivity to fertilizer TN inputs

Sensitivity to manure TN inputs

1. APEX – CEAP: Ratio between output and input (No-practice, 2006, and 2011 scenarios including all input sources in cropland areas)
 2. SPARROW: source specific coefficient (Various studies in the Chesapeake bay and Northeastern and Mid-Atlantic regions) *
 3. Phase 5.3.2: Ratio between input and output, slope of multivariate regression, and slope between output and input (14 scenarios , hwm, hom, lwmm, alf, and hyw)
- * Preston and Brakebill (1999), Ator et al. (2011), Moore et al. (2011), and Preston et al. (2011).

Sensitivity implementation on phase 6

- Total nitrogen sensitivities from other existing models support the Phase 532-AGCHEM findings.
- Phase 532-AGCHEM sensitivities are available not only for TN but also by nitrogen species.
- Phase 532-AGCHEM DIN and organic nitrogen sensitivities have been implemented in phase 6.

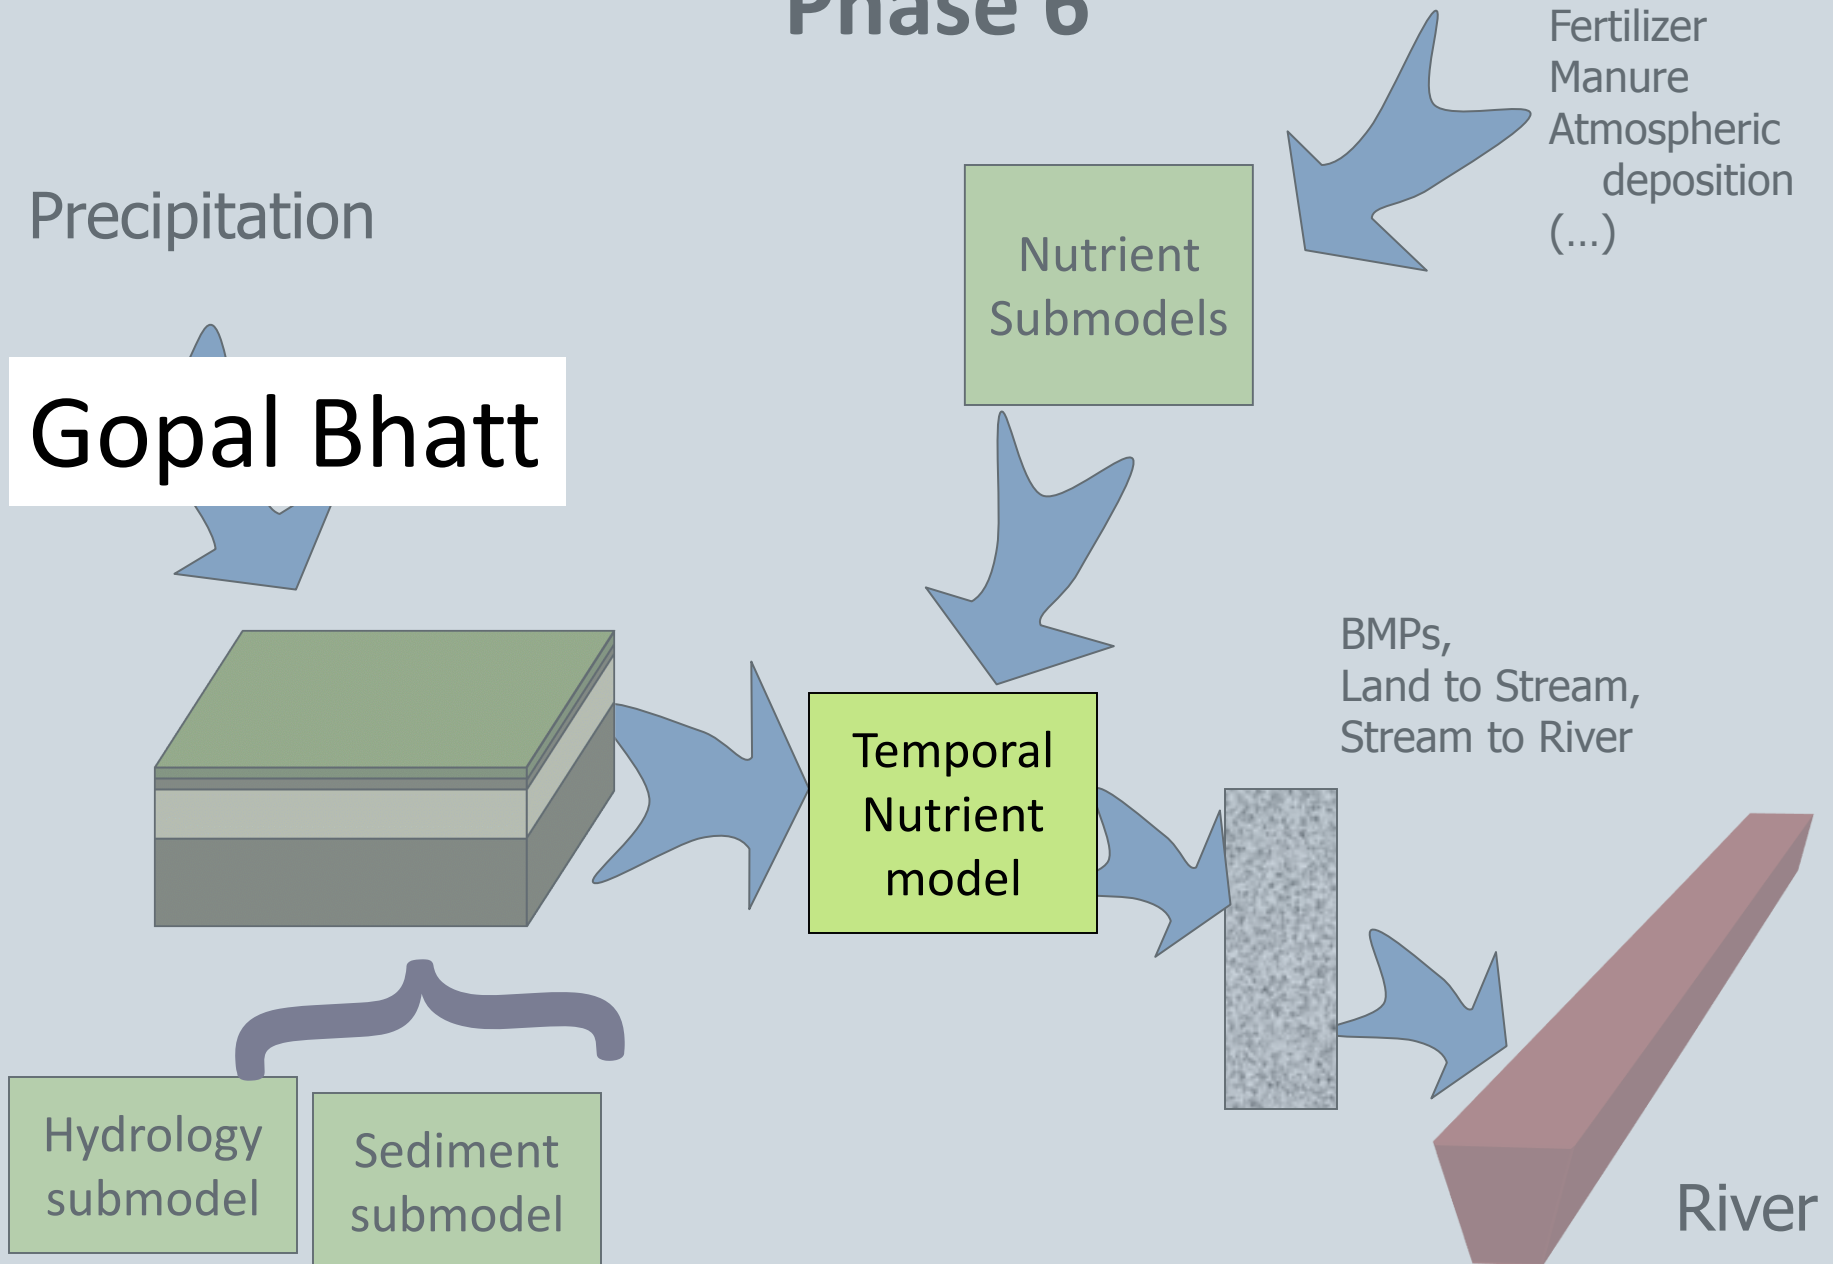

Decide on Phase 6 nitrogen sensitivities

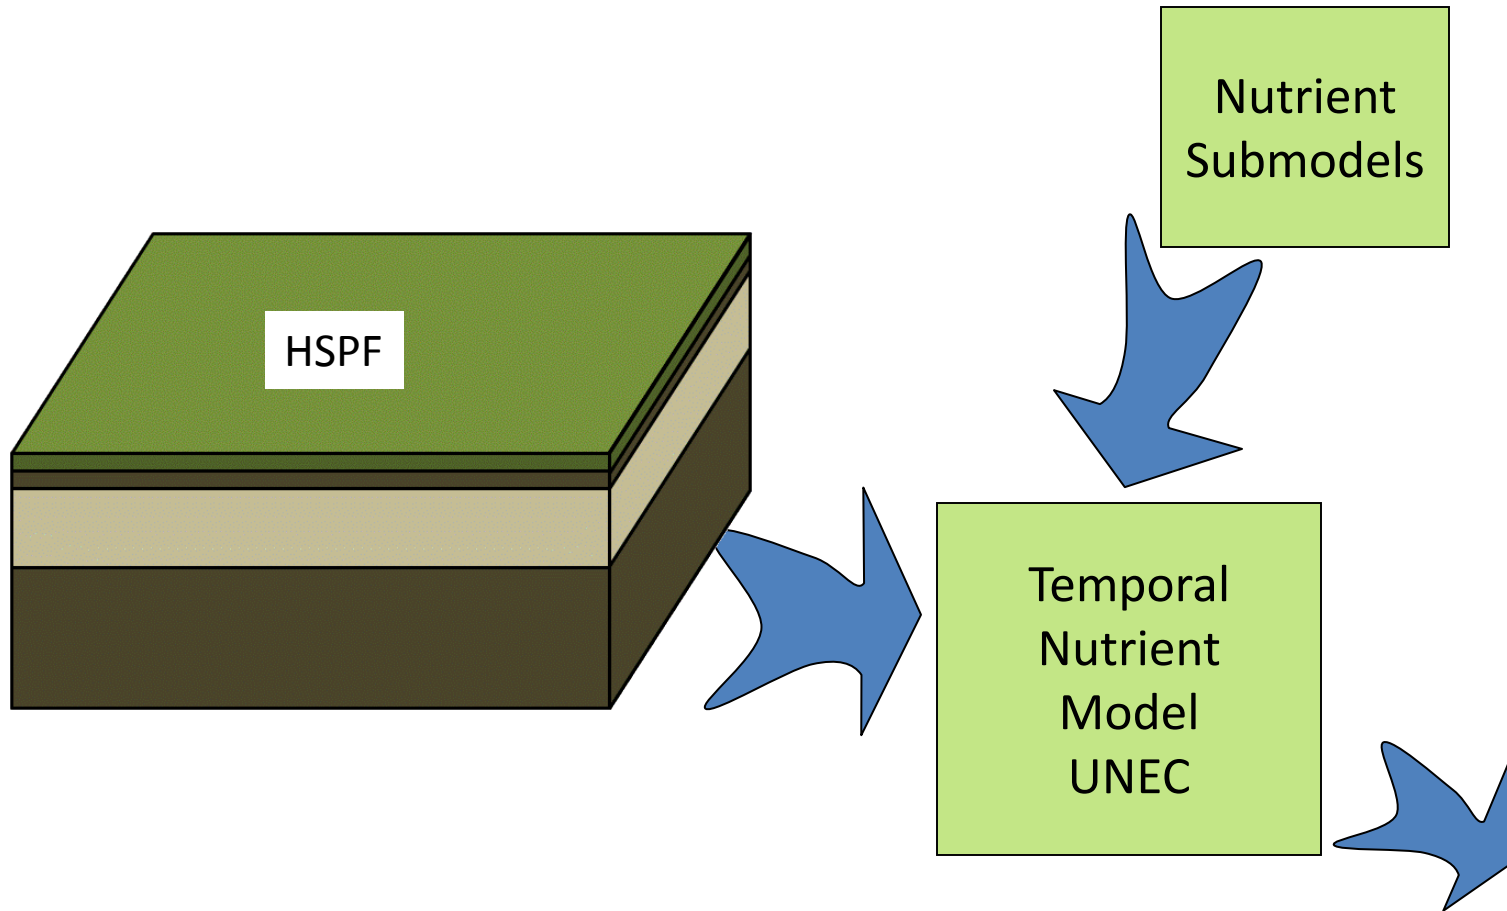

- Phase 532-AGCHEM sensitivities are more extensive and robust than other models sensitivities.
- The new recommendation is to adopt the Phase 5.3.2 AGCHEM nitrogen sensitivities.
- Please review both the Phase 5.3.2 AGCHEM and multiple model sensitivity analyses in order to make a decision.

Unit Nutrient Export Curve (UNEC)

An examination of **transit time distribution**

Unit nutrient export curve stochastically describes transport of nutrients as a probability density function. In other words, transit times are variable for inputs applied at same time.

Here, a unit nutrient export curve is described using **one** parameter. This parameter would be obtained from mean transit times estimated from models (e.g. MODFLOW, APLE) and observations.

Dirac-delta / Pulse input

(1) Unit Nutrient Export Curve

(2) Nutrient Input

(3) Aggregate Nutrient Export

(4) Transit Time Distribution, $t = 1$ months

Dirac deltas / Pulse inputs

UNECs are superimposed to obtain the output as the convolutions of inputs.
