

# **Analysis of Chesapeake Bay Marine Discharges**

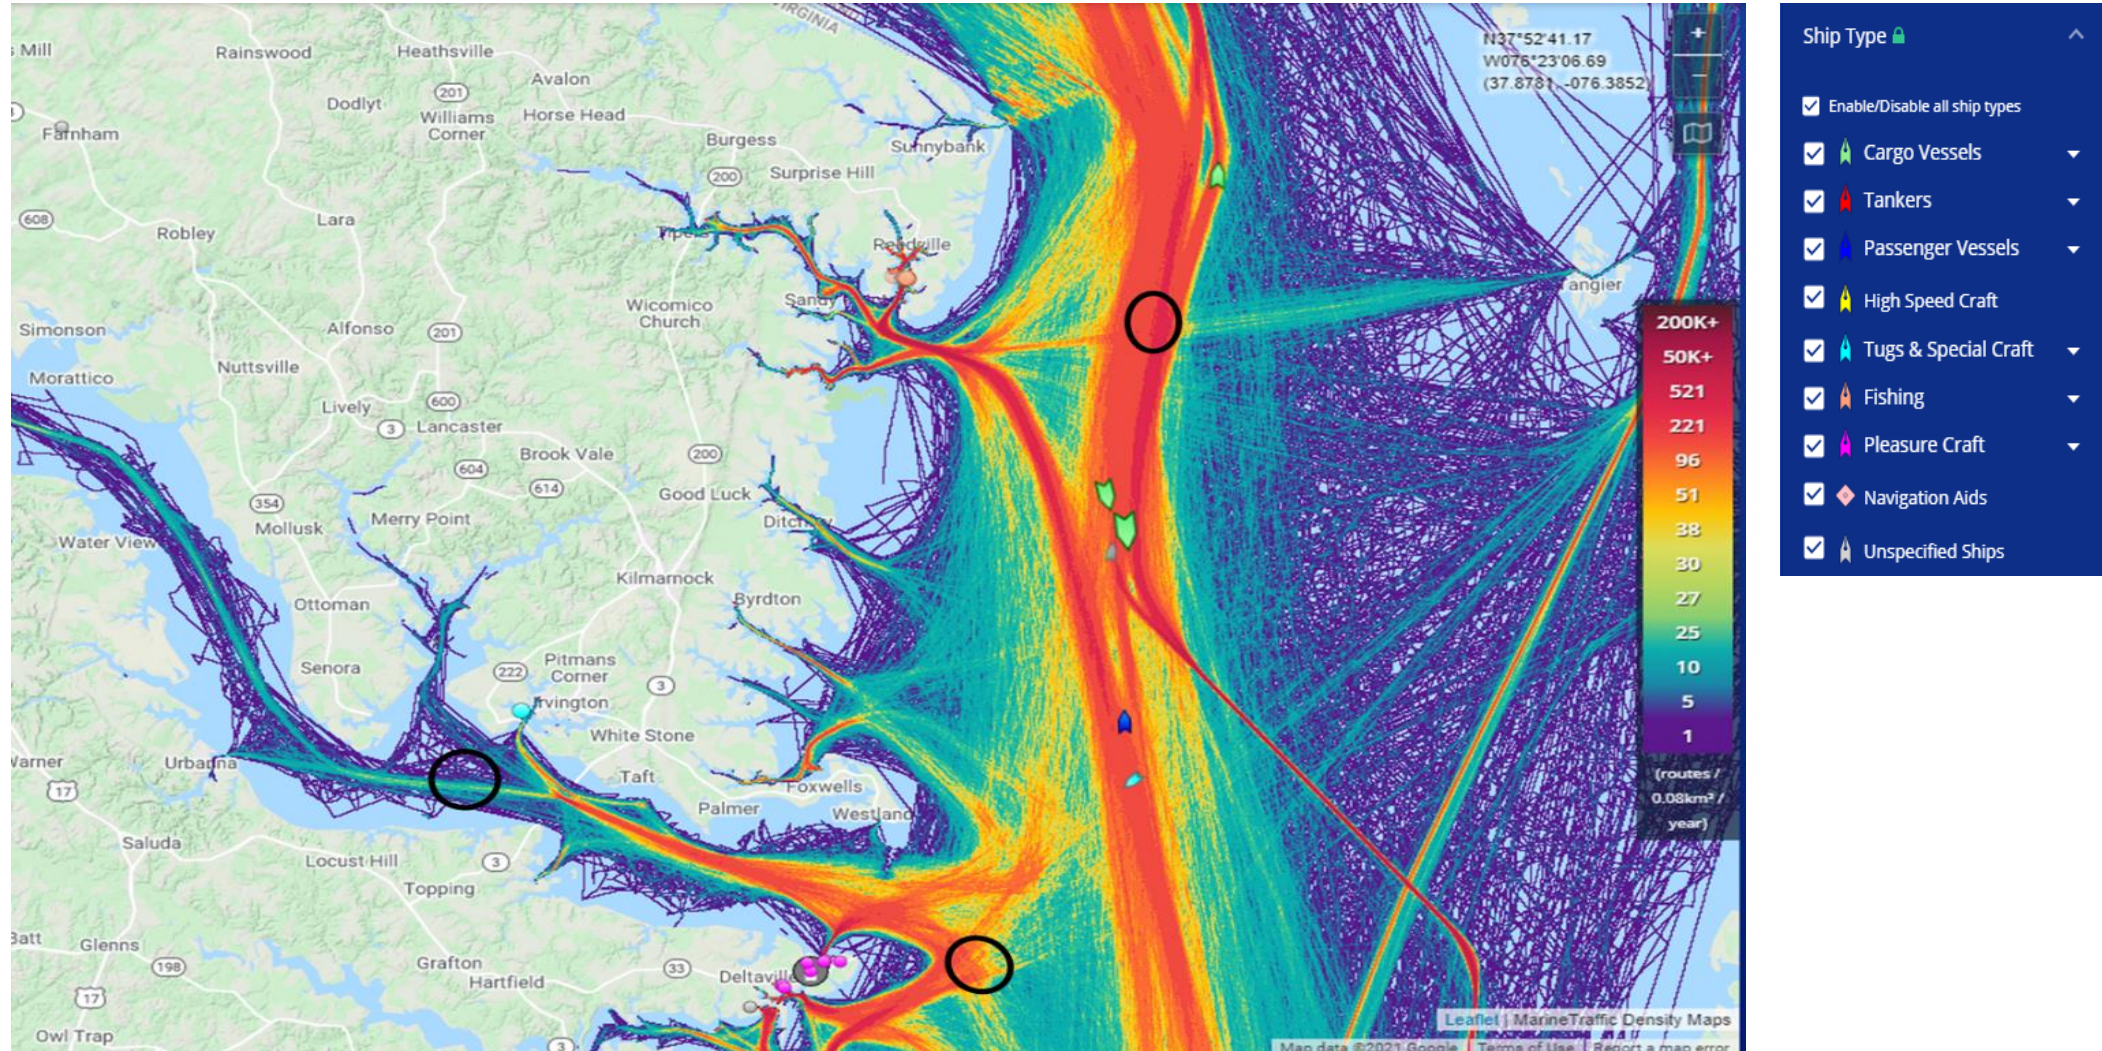

**Richard Tian, UMCES**  
**Lew Linker, EPA-CBPO**

**Modeling Quarterly Review**  
**04/07/2021**  
**Annapolis**

# INTRODUCTION

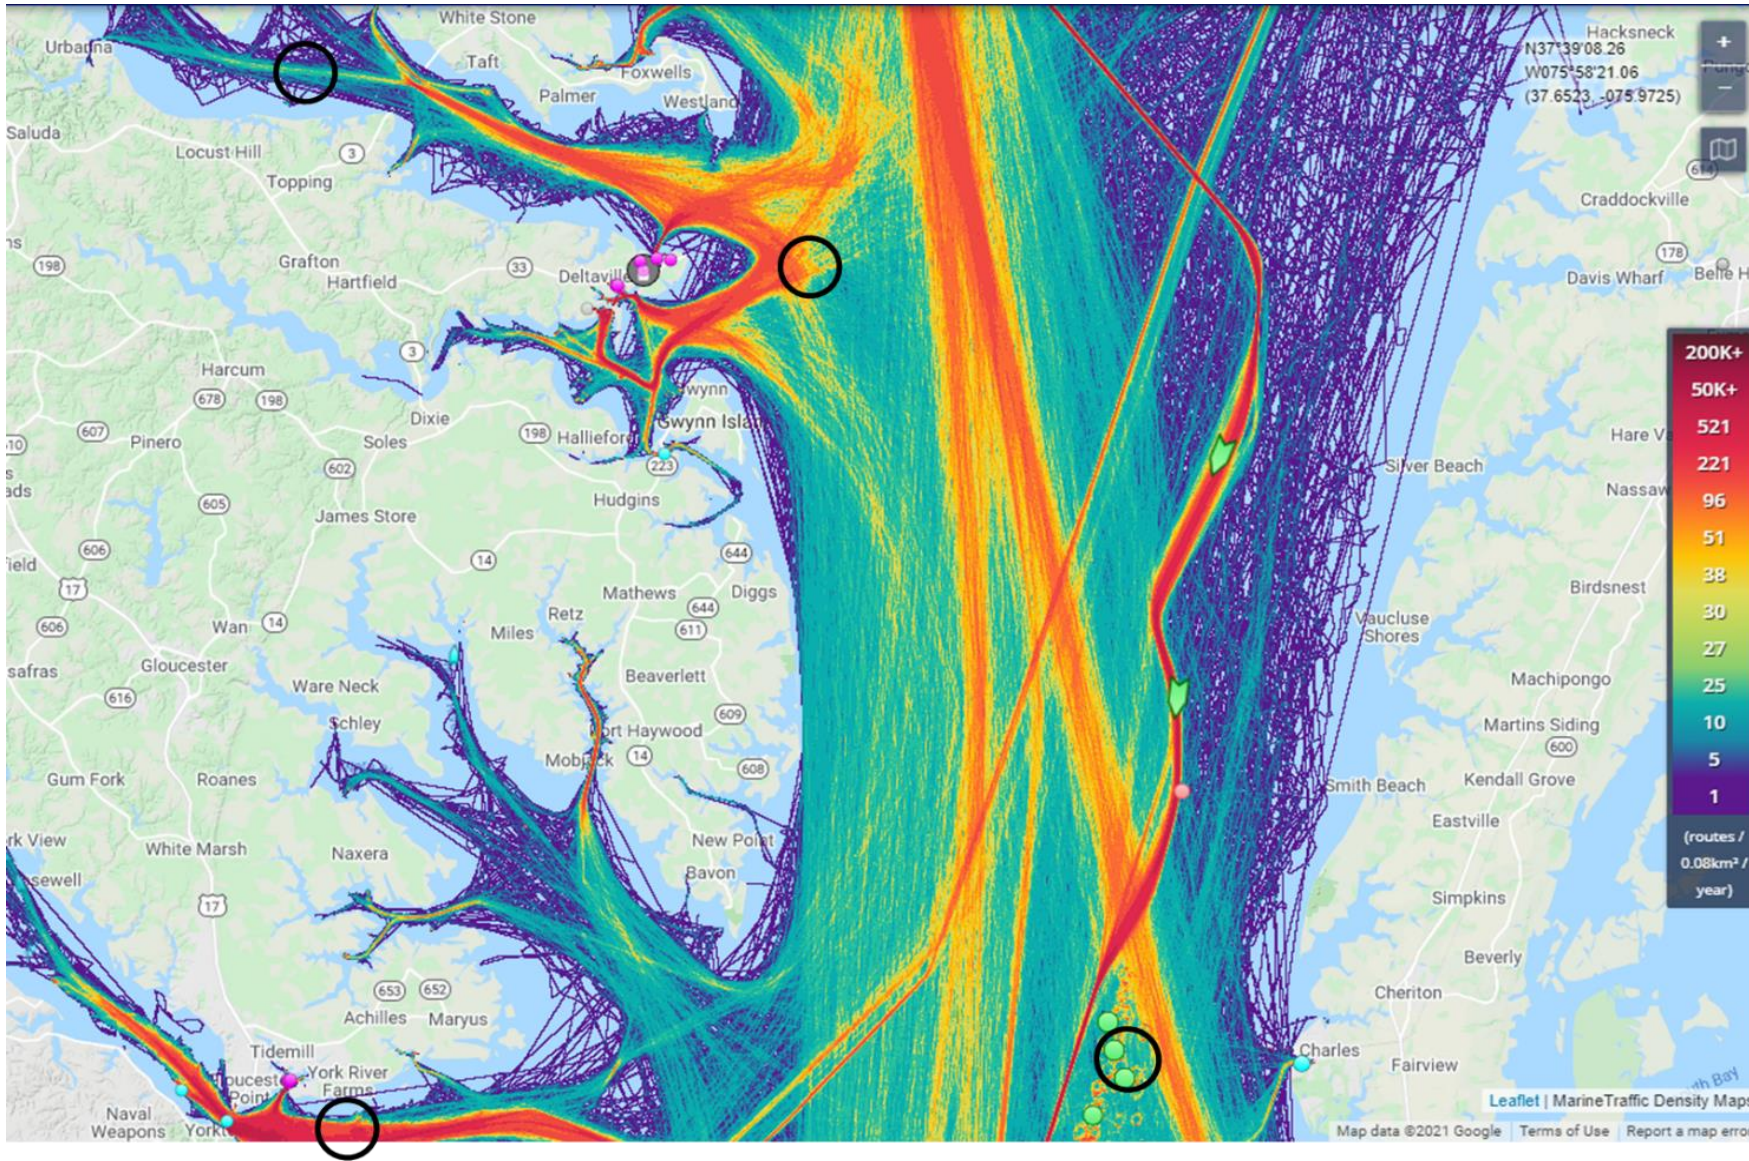

- **A VA DEQ project**
- **Establishing No-Discharge Zones (NDZ) to protect sensitive area**
- **The primary concern is fecal coliforms.**
- **Identify influential area using model tracer analysis**

# AIS vessel density map of the Northern Neck area. Black open circles are proposed discharge locations (from DEQ)

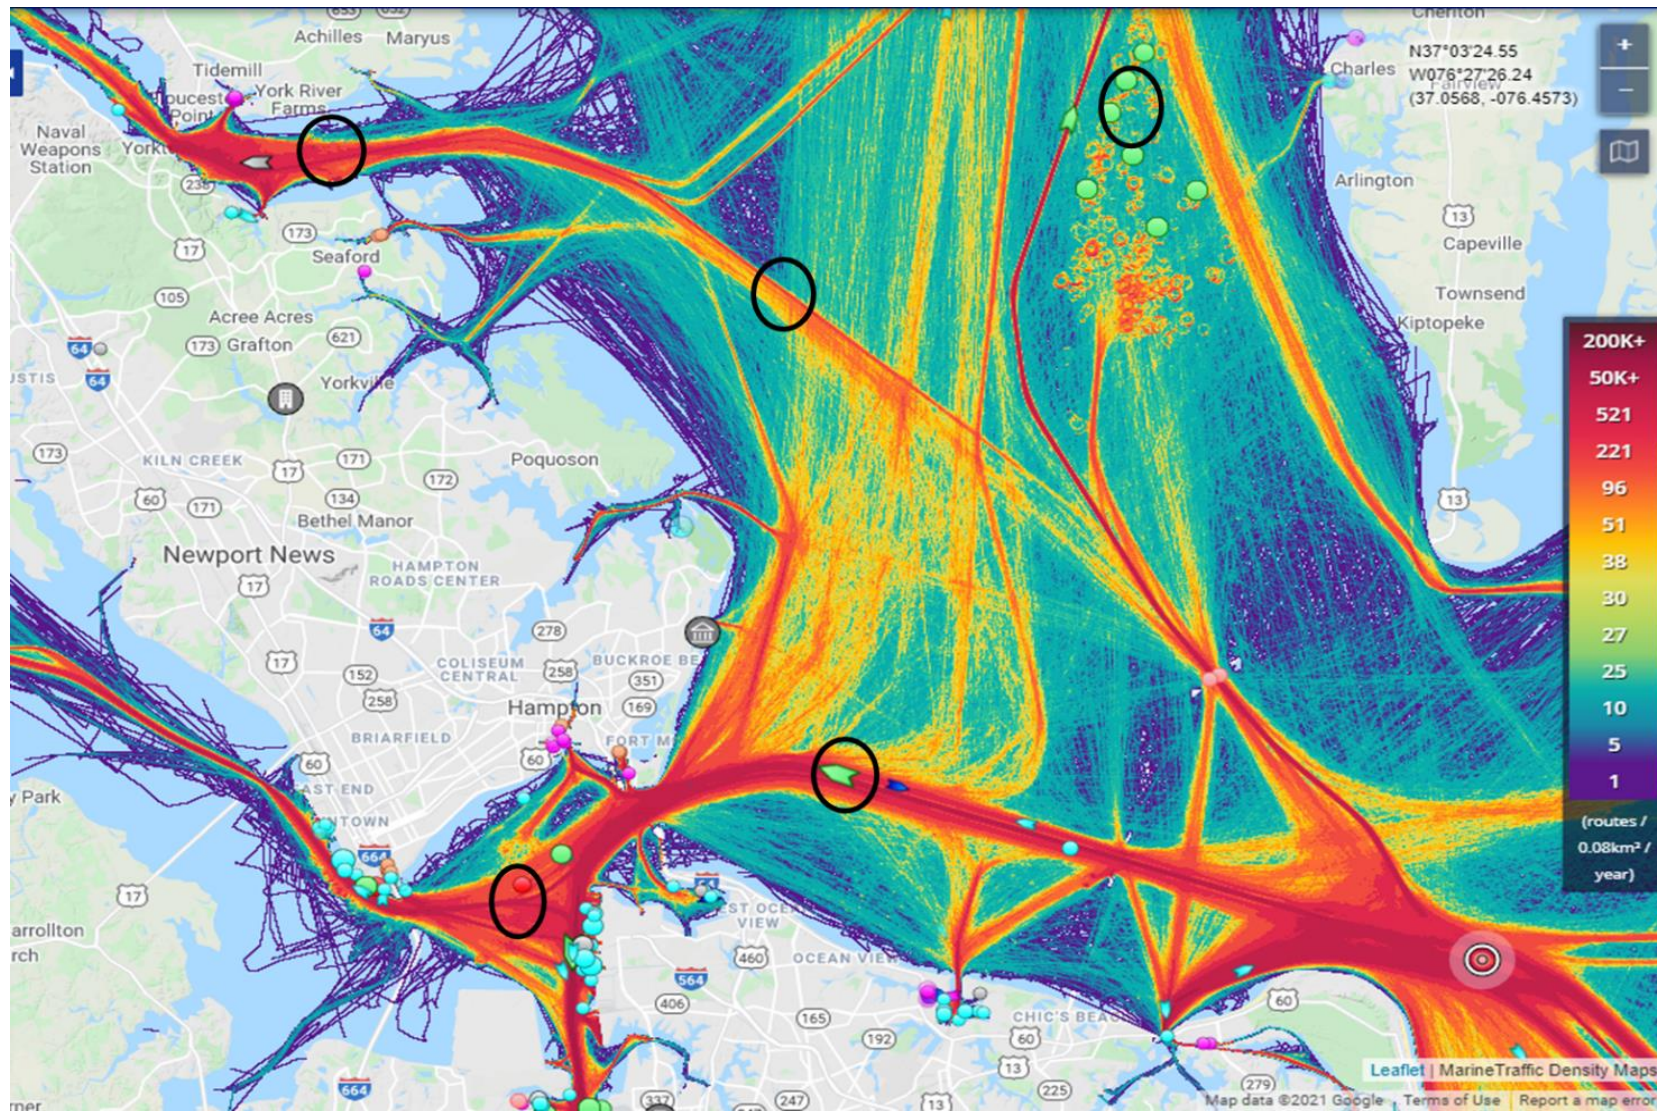

**AIS vessel density map of the Middle Peninsula area. Black open circles are proposed discharge locations (from DEQ).**

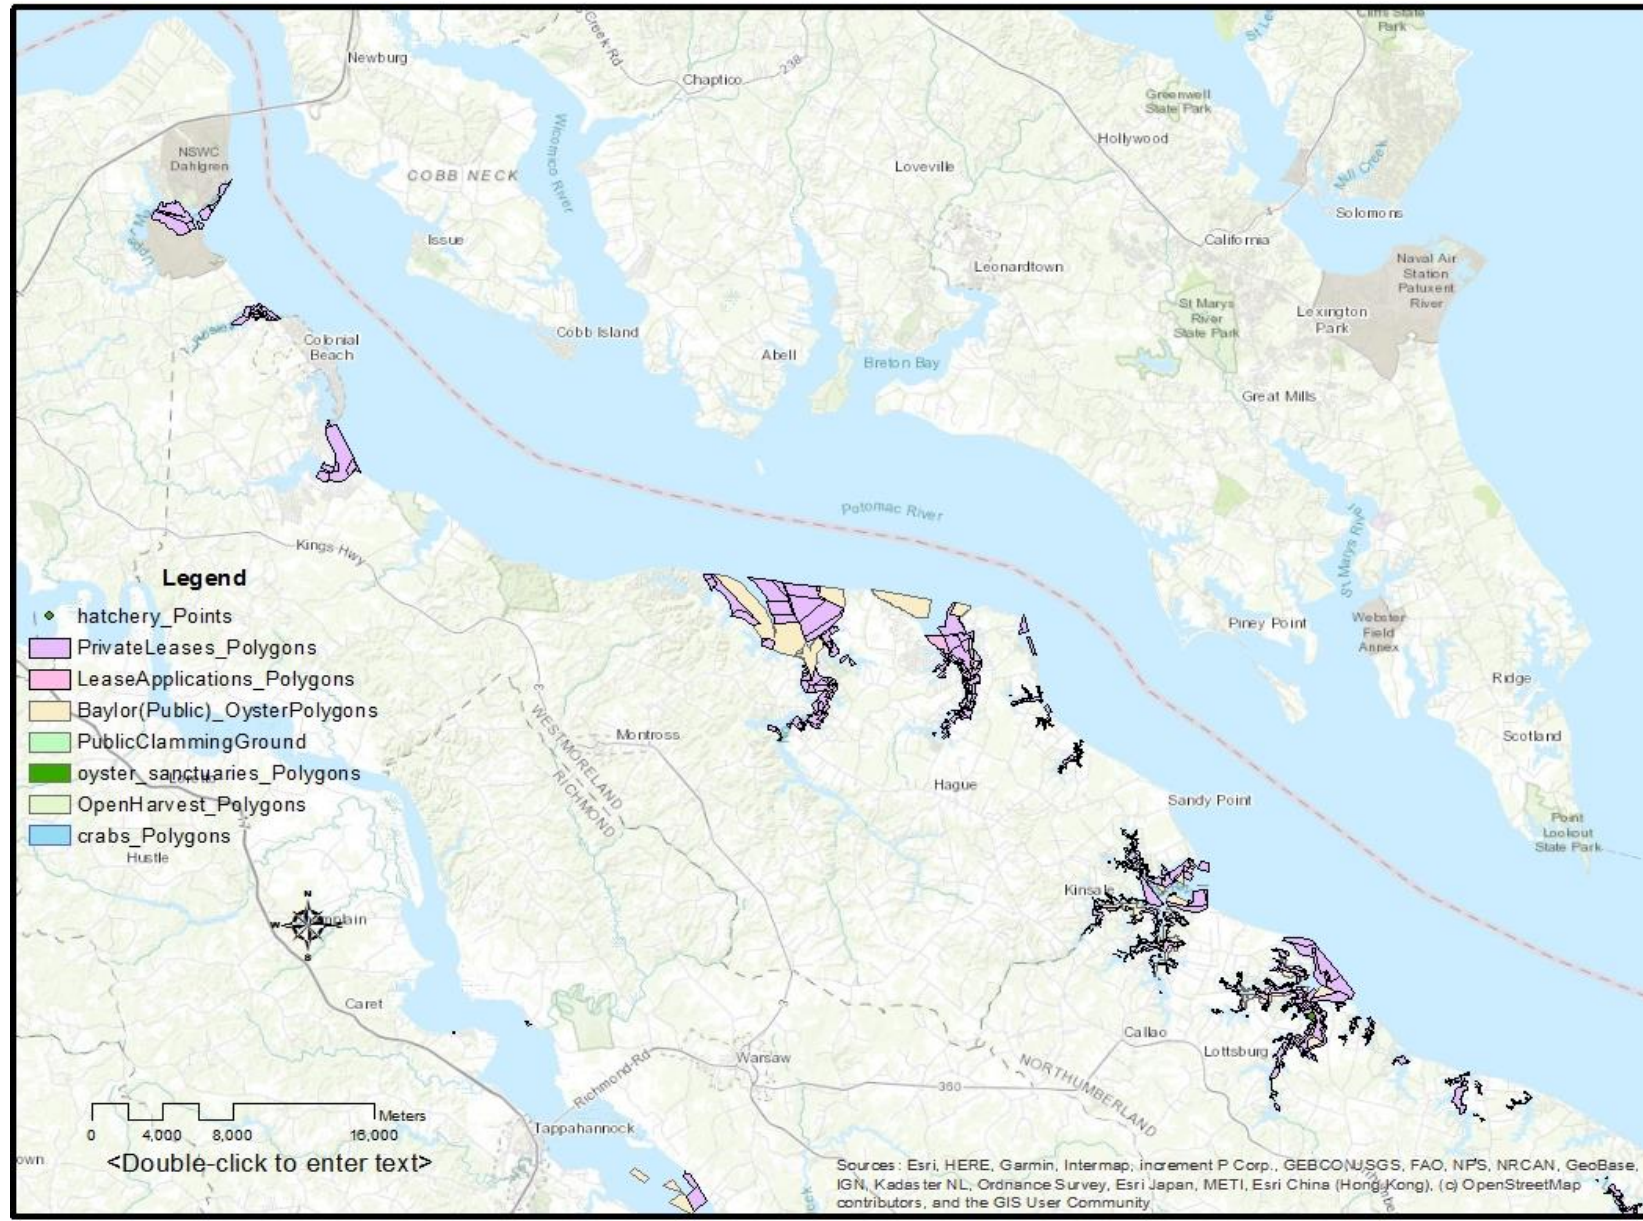

**AIS vessel density map of the Hampton Roads/Tidewater area.  
Black open circles are proposed discharge locations (from DEQ).**

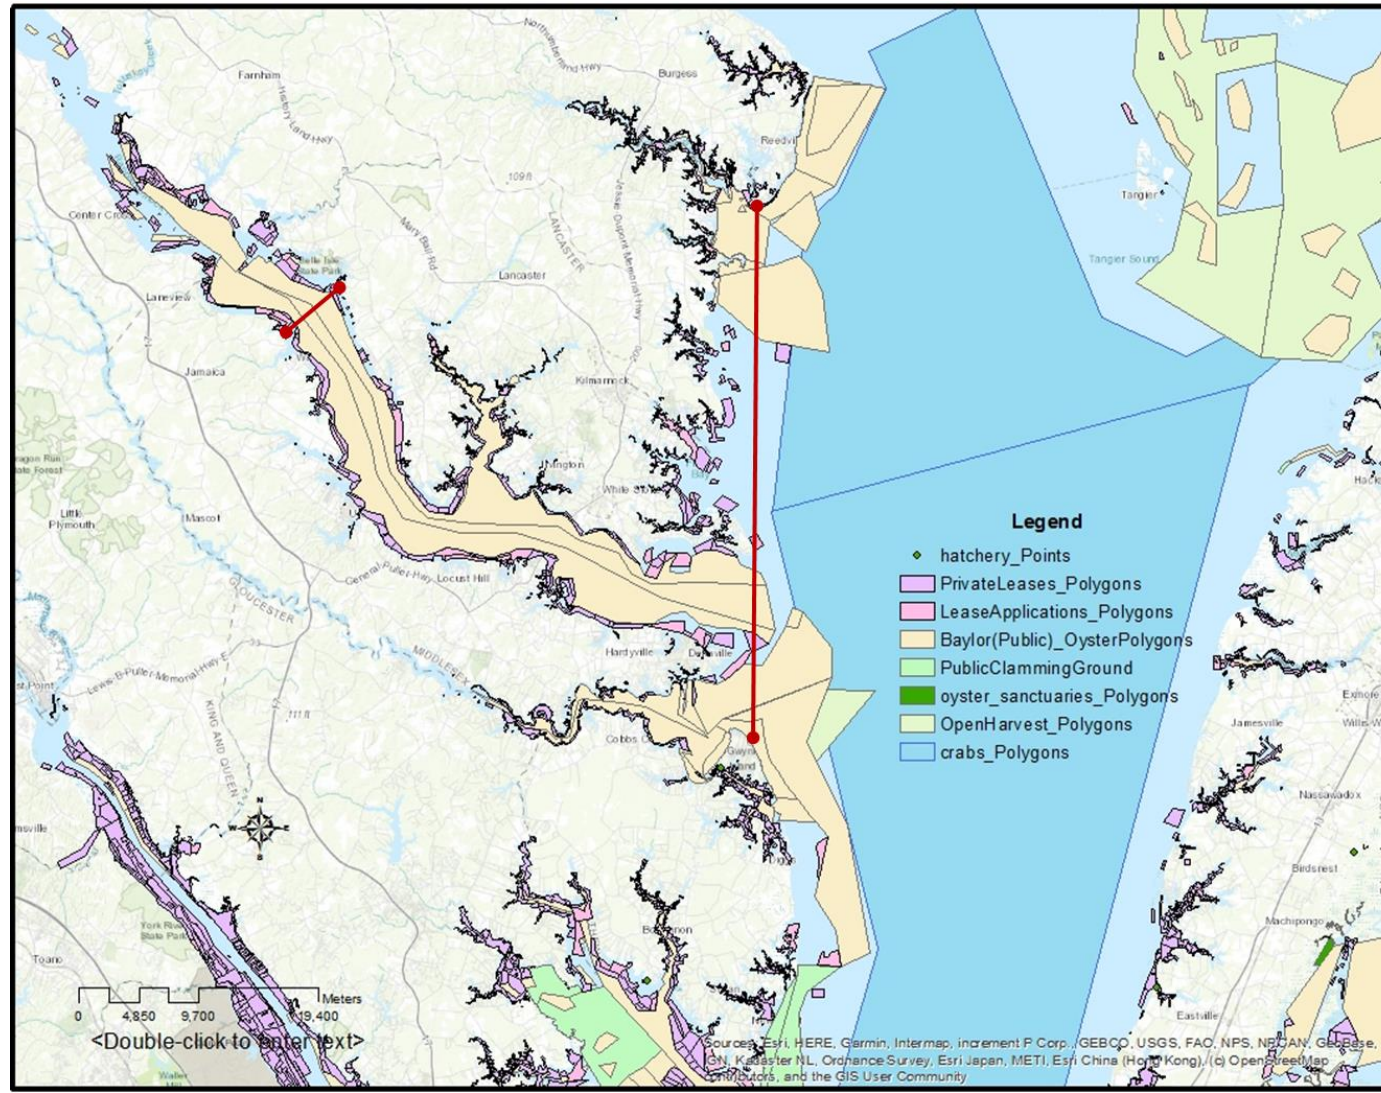

# Western Northern Neck shellfish leases and grounds (from DEQ)

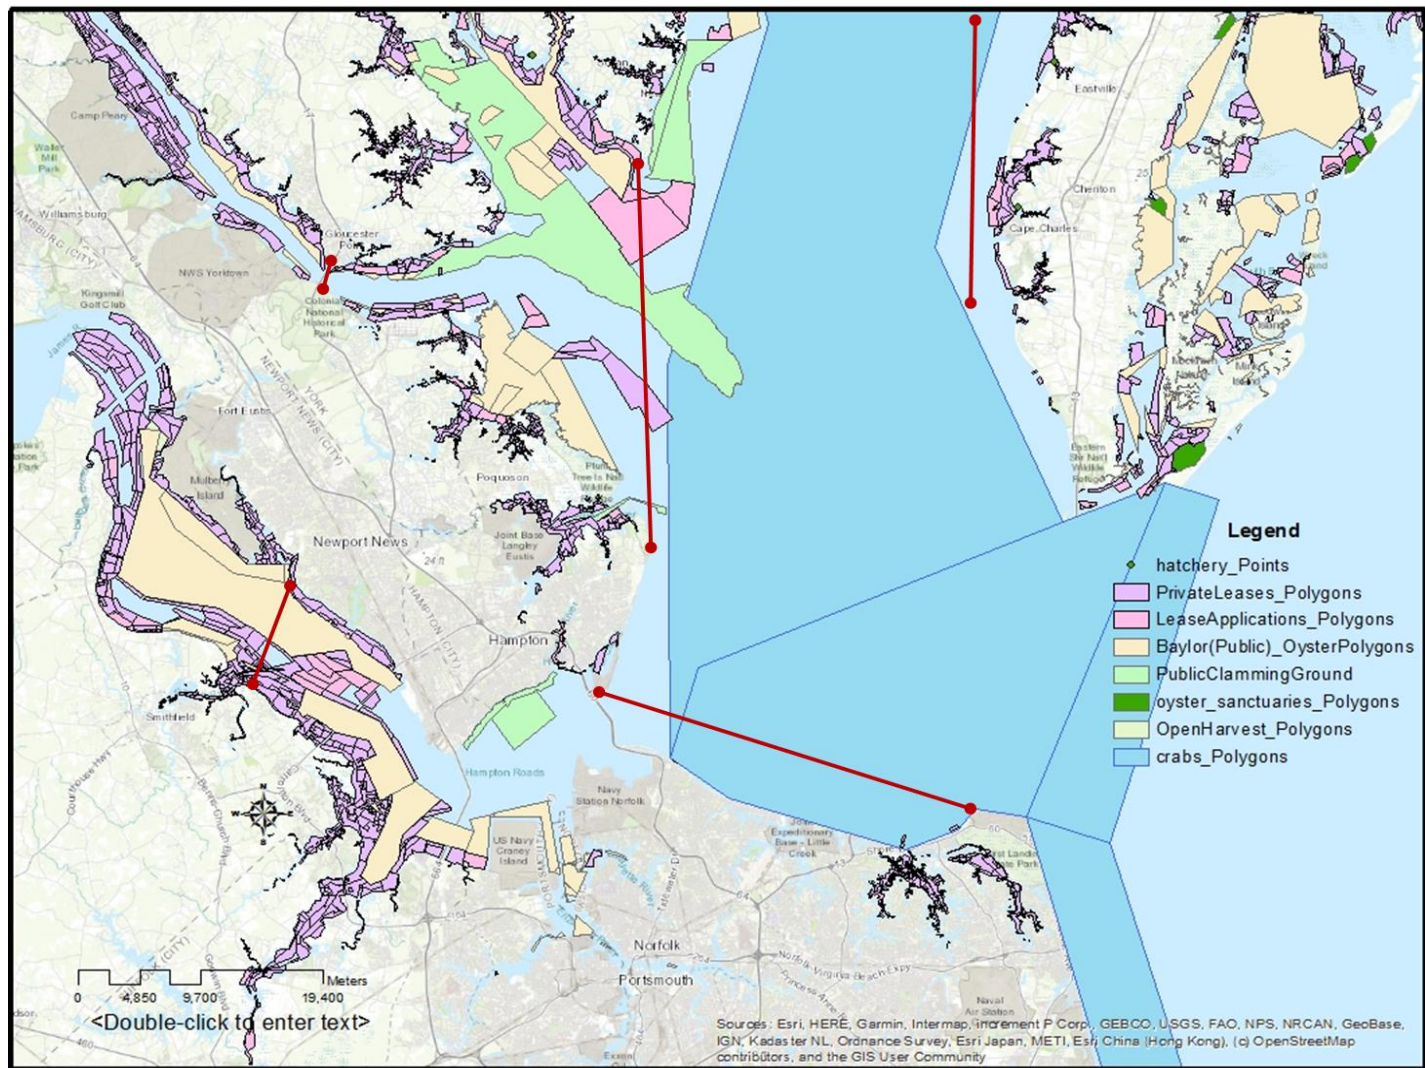

**Northern Neck and northern half of middle peninsula shellfish leases and grounds. Two proposed gates are illustrated with red bars.**

# Southern Bay and tributaries shellfish leases and grounds. Five proposed gates are illustrated with red bars.

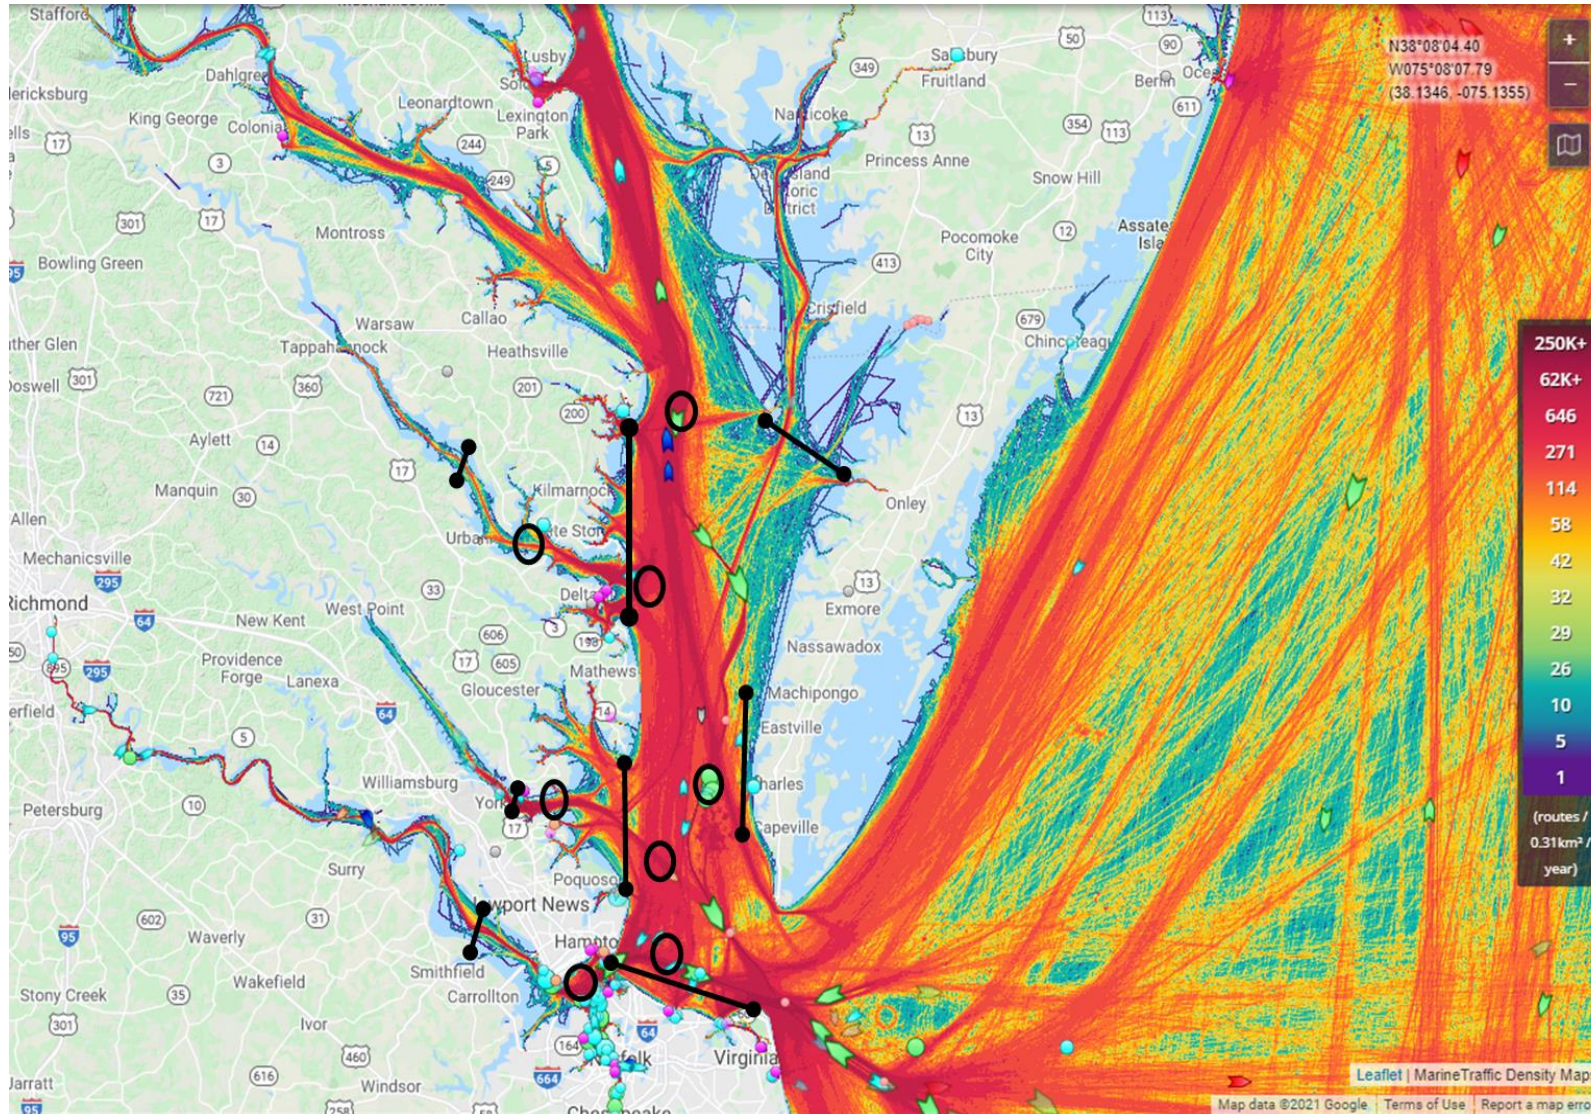

**Proposed gate locations were selected based on a number of factors including:**

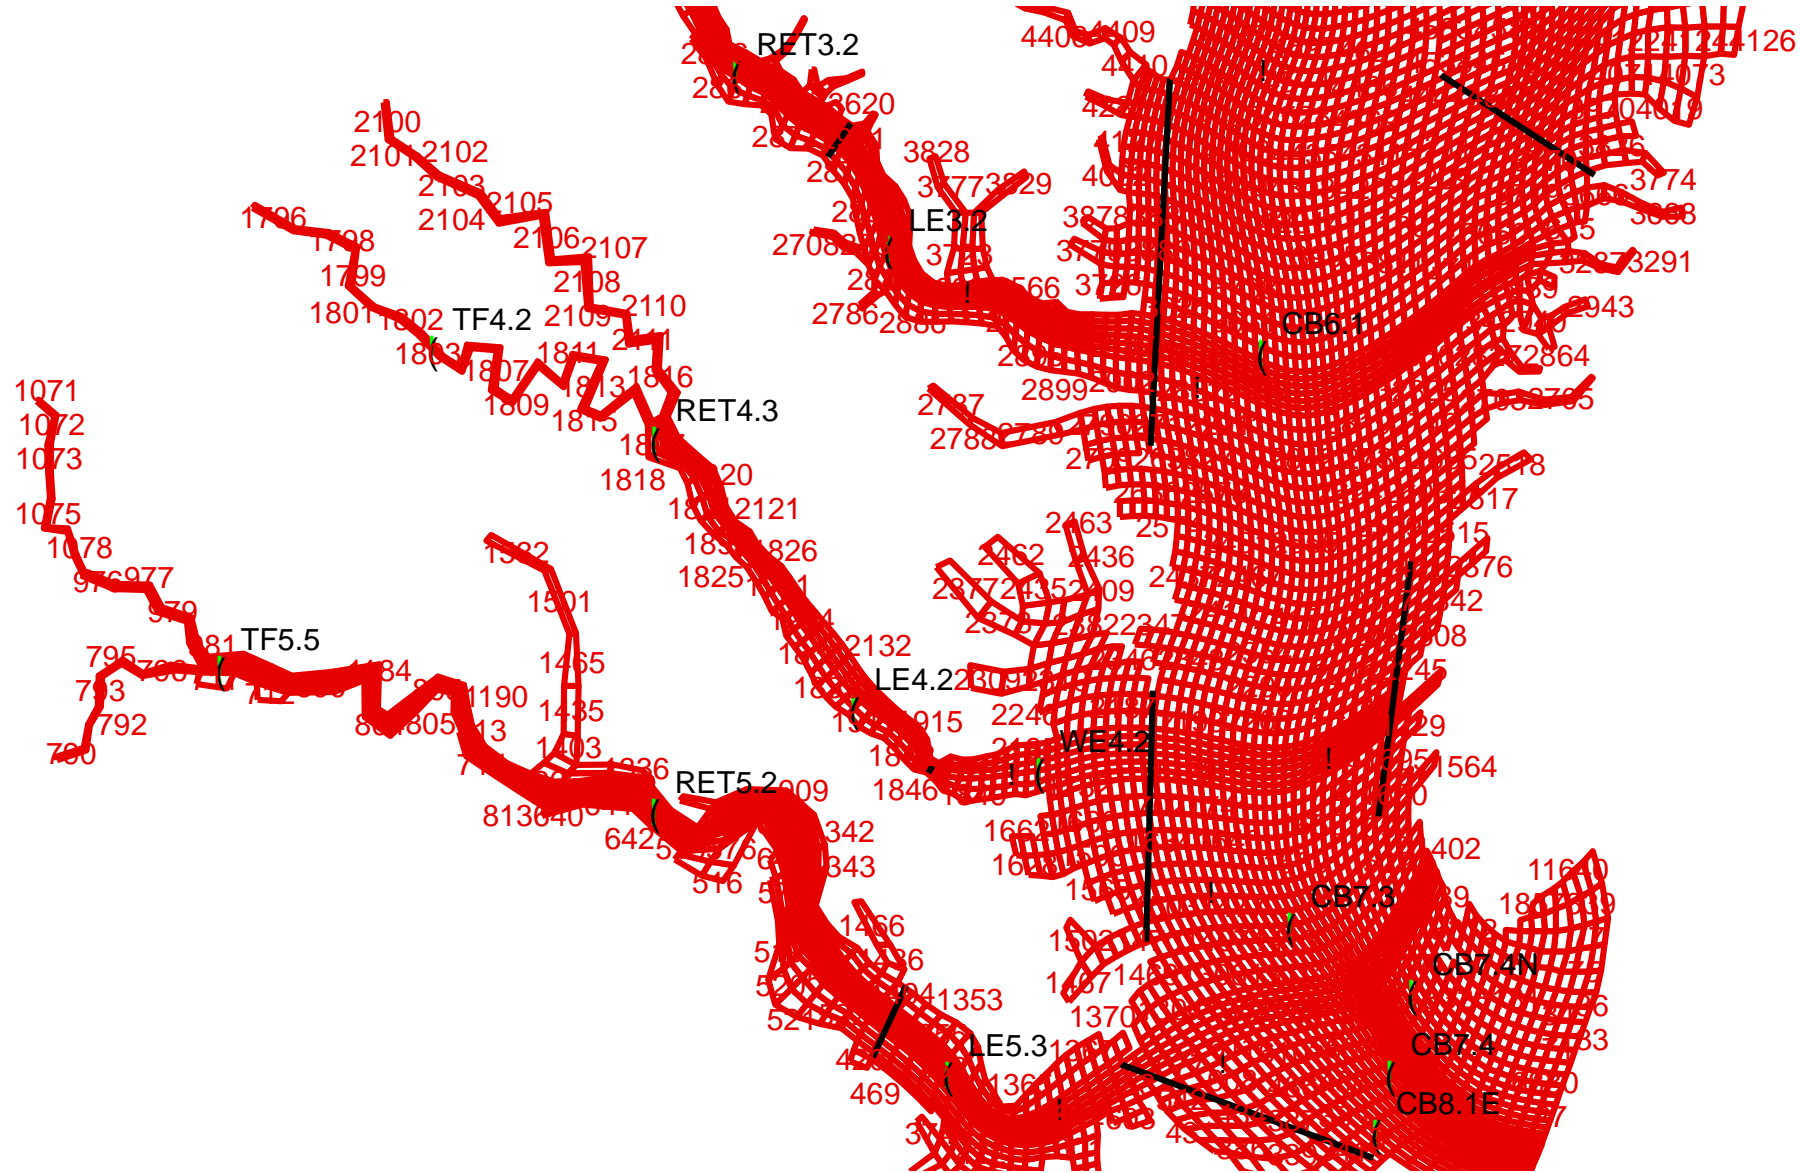

- Presence of shellfish leases and public shellfish grounds**
- VDH shellfish closures (Virginia Department of Health)**
- Slow to intermediate flushing rates**
- State parks and public beaches**

**All proposed discharge locations are illustrated with a black, open circle. All proposed gates are illustrated with a black bar.**

# Discharge locations and tracer flux gates on the model grid

## Gates along the grid versus crossing the grid

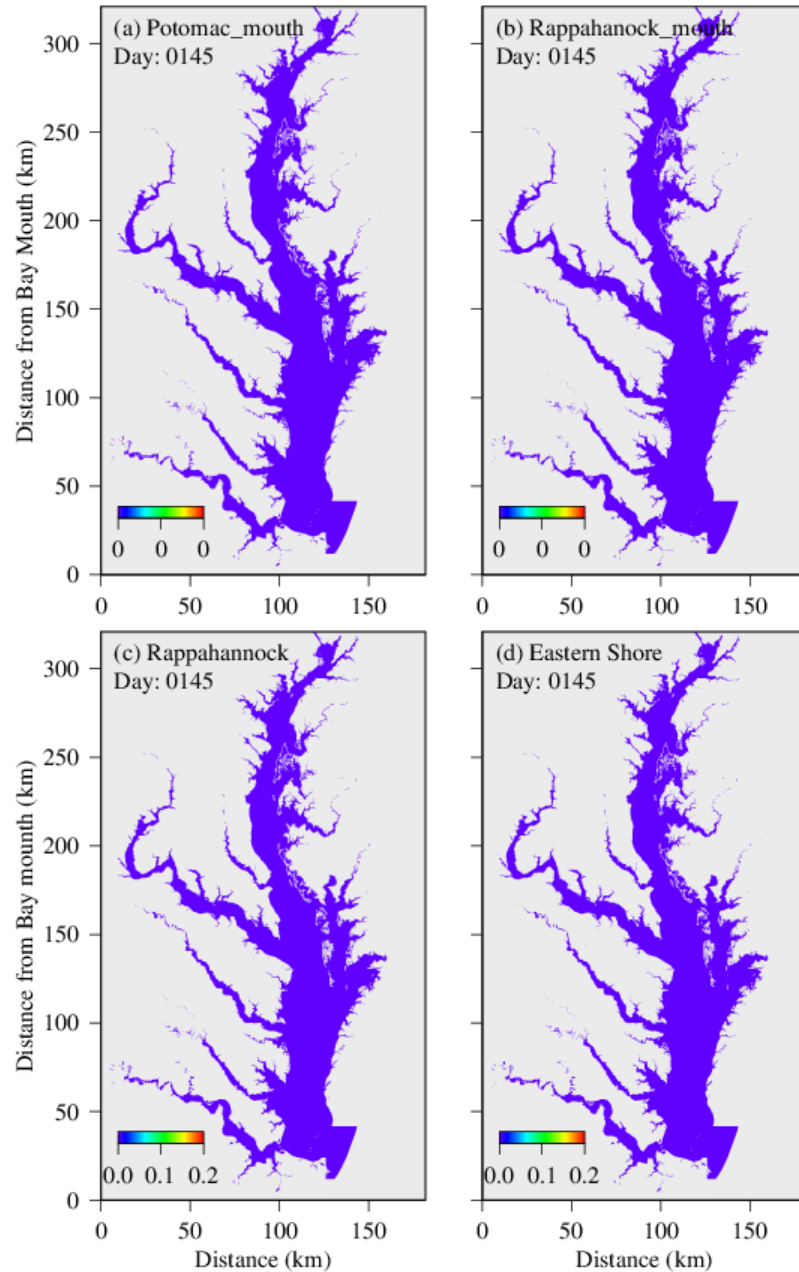

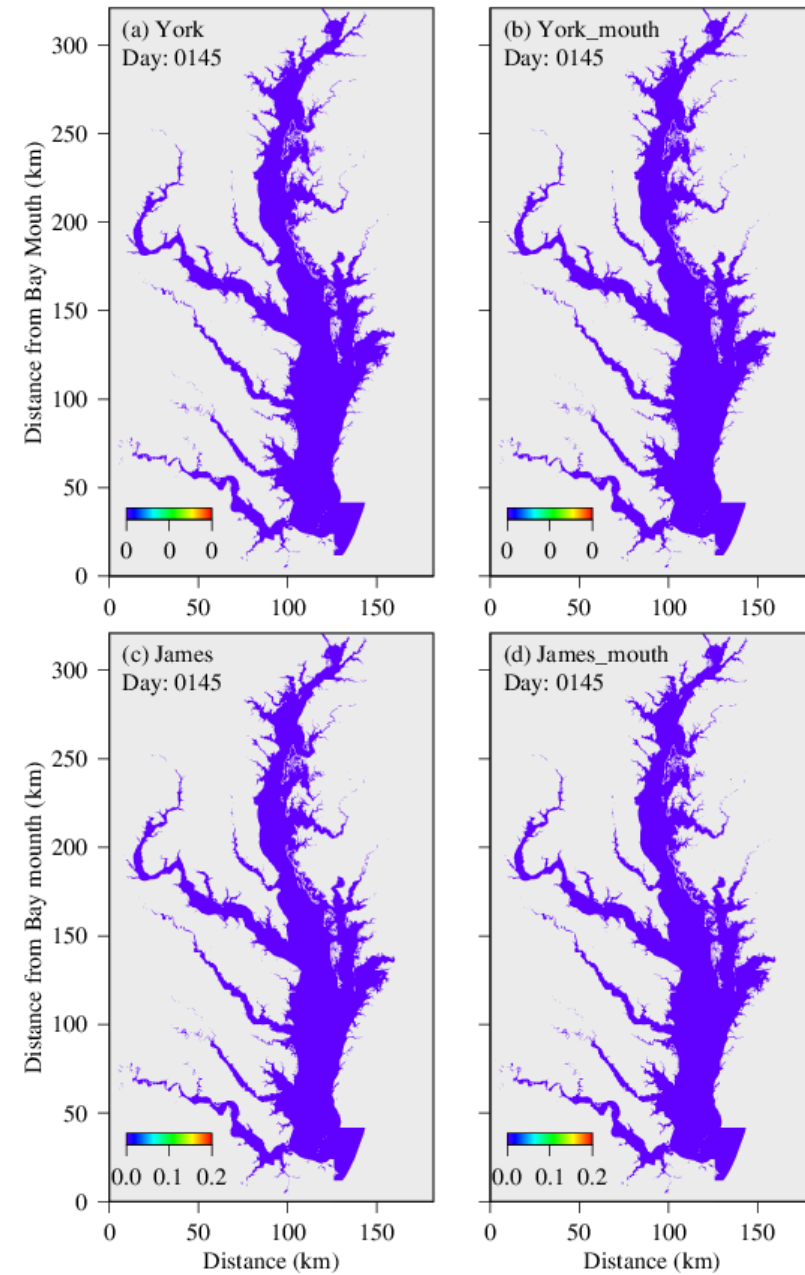

## **A test case**

- **1994 hydrodynamics**
- **Tracer continuously released from Jun. 1 through Sep. 31.**
- **500k pounds per day**
- **Model ran 2 years from 1994 to 1995**
- **Movie stopped at the end of 1994.**

# Assumptions and outstanding questions

- The simulation will include a conservative (persistent), neutrally buoyant tracer.
  - Is it possible to include some decay rate (and sinking) in the tracer to be representative of enteric bacteria die off?
- All discharges would release and be tracked independently at each gate over some simulation period.
  - Will the discharge be set up as a one-time discharge or as a continuous release at a defined rate?
  - Is it possible to have a variable discharge rate through the simulation (heavier on weekends in the summer)?
- The conditions under which the simulation takes place should consider critical conditions (e.g. summer).
  - What are our options for seeing the effect of variable flow and weather?
  - Will the current modeling assumptions for a ten-year meteorological and hydrodynamic cycle (the “average” conditions) be used in the simulations?
